

1 Quantifying Population Exposure to Airborne Particulate Matter During Extreme Events
2 in California due to Climate Change

14 **Supporting Information**

15

16 Figure S1 shows the future change (%) in population-weighted annual average
17 concentrations of PM_{0.1} in the future (2047-53) compared to the present-day (2000-06)
18 for California and the three air basins of interest. The population-weighted annual
19 average concentration of PM_{0.1} total mass was predicted to decrease by ~9% in California
20 during future years (2047-53) relative to present years (2000-06) with the majority of this
21 change occurring in the SoCAB (Fig. S1). Primary PM_{0.1} source contributions to EC and
22 OC concentrations decreased in the SV but increased in the SJV and SoCAB. Secondary

23 PM_{0.1} component concentrations decreased in the SoCAB with mixed results in the SV
24 and SJV.

25

26 Figure S2 shows the future change (%) in population-weighted annual average
27 concentrations of PM₁₀ in the future (2047-53) compared to the present-day (2000-06) for
28 California and the three air basins of interest. Patterns for PM₁₀ total mass, component
29 species, trace metals, and contributions from different sources were similar to PM_{2.5}
30 patterns. PM₁₀ total mass was predicted to decrease by ~3% in California in the future.
31 Concentrations of EC, OC, S(VI), and N(-III) were predicted to decrease in the range
32 between ~1-4%. Population-weighted concentrations of trace metals, and contributions
33 from different sources were also predicted to decrease in the future by as much as ~3-6%.

34

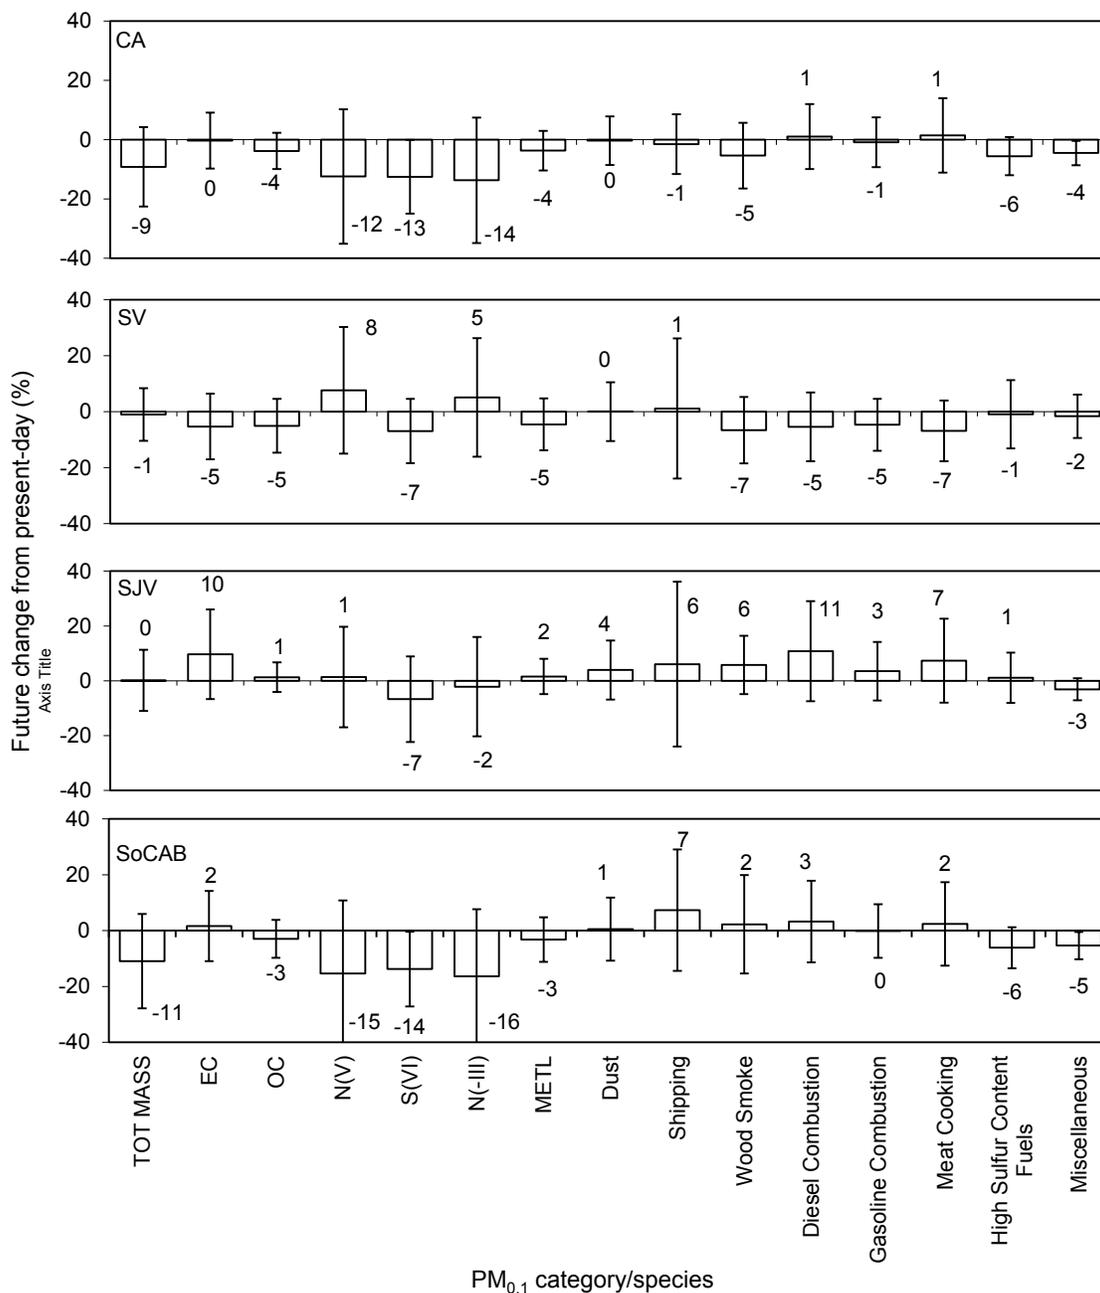

35

36 Figure S4 illustrates the Generalized Pareto Distribution (GPD) fit to PM_{2.5} total mass
37 concentrations in present and future climate. Basecase emissions inputs to both scenarios
38 are identical. Concentration differences are caused by the direct effects of meteorology
39 on the air pollution system.

40

41 Figure S5 displays the global climate change impact on 10-year return level for
42 population-weighted 24-hour average PM_{0.1} concentrations based on the Extreme Value
43 Theorem (EVT). The plots show % difference between the future (2047-53) and present
44 (2000-06) with vertical bars corresponding to 90% confidence interval for the 10-year
45 return level estimates. Whenever the CI bars span zero, it implies that the predicted

46 change in the future is not likely to be statistically significant. . The 10-year return level
47 of population-weighted 24-hour average $PM_{0.1}$ is generally going to decrease for total
48 mass, and speciated $PM_{0.1}$ for California in future, although these are not likely to be
49 statistically significant. Among the air basins of interest, only the SJV shows slight
50 increase in 10-year return level values for difference sources, however, these changes are
51 not statistically significant as the CI bars overlap zero. Figure S5 displays the climate
52 effects on 10-year return level population-weighted 24-hr average PM_{10} concentrations
53 during extreme events based on the EVT. 10-year return levels of 24-hr average
54 population-weighted concentrations of PM_{10} total mass, chemical species except sulfate,
55 trace metals and primary source contributions are predicted to increase in the future for
56 the SJV and SoCAB. The 10-year return level population-weighted daily average total
57 mass concentration of PM_{10} was predicted to increase by 19% in California, 15% in the
58 SV, 13% in the SJV and only 1% in the SoCAB. Once again, the 90% confidence
59 interval spans zero for the majority of these results relative to the inter-annual variability.
60 The only statistically significant trends displayed in Fig. S5 are an increase in the 10-year
61 return level population-weighted concentrations of primary diesel PM (state-wide).

Fig. S1. Future (2047-53) change in population-weighted annual-average concentrations of PM_{0.1} total mass, primary and secondary components, trace metal and source categories contributing to the total mass from present-day (2000-06). Panels (top-down) show California state-wide, Sacramento Valley (SV) air basin, San Joaquin Valley (SJV) air basin, and South Coast Air Basin (SoCAB) average results. The error bars represent the lower and upper limits of the 90% CI.
