1 **Figures and Tables**

2 **Figure S1:** Purging the volatile 1,4-dihydroxy-2-methyl-2-butene impurity from *cis*  $\beta$ -IEPOX  
3 droplets with dry N<sub>2</sub> over a heated bulb (60°C) for several hours. The fraction of impurity to  
4 IEPOX, as measured by CIMS, was allowed to decay to < 2% before use for experiments.

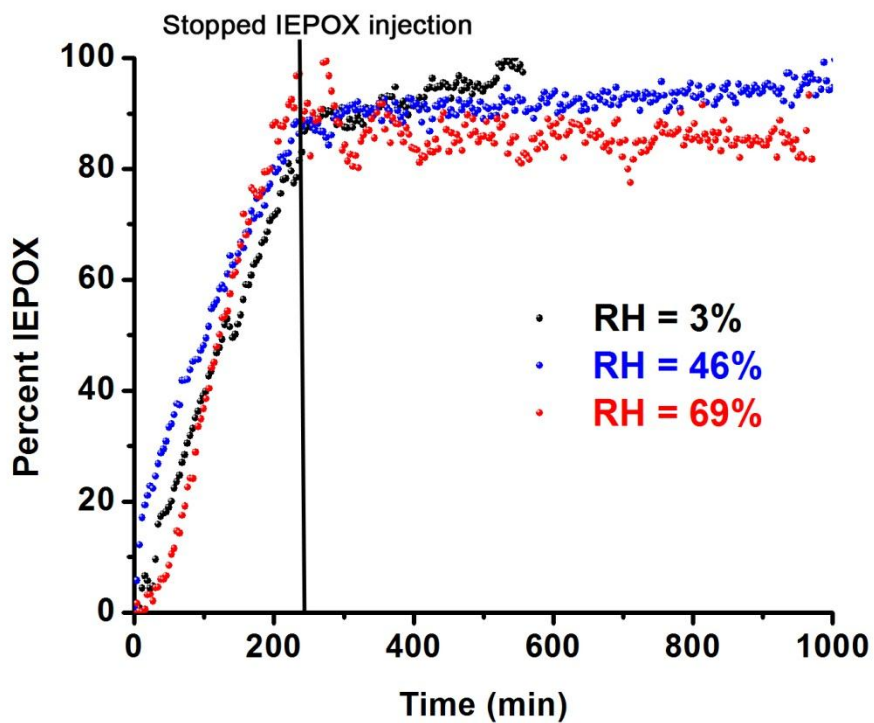

5

6

7

8

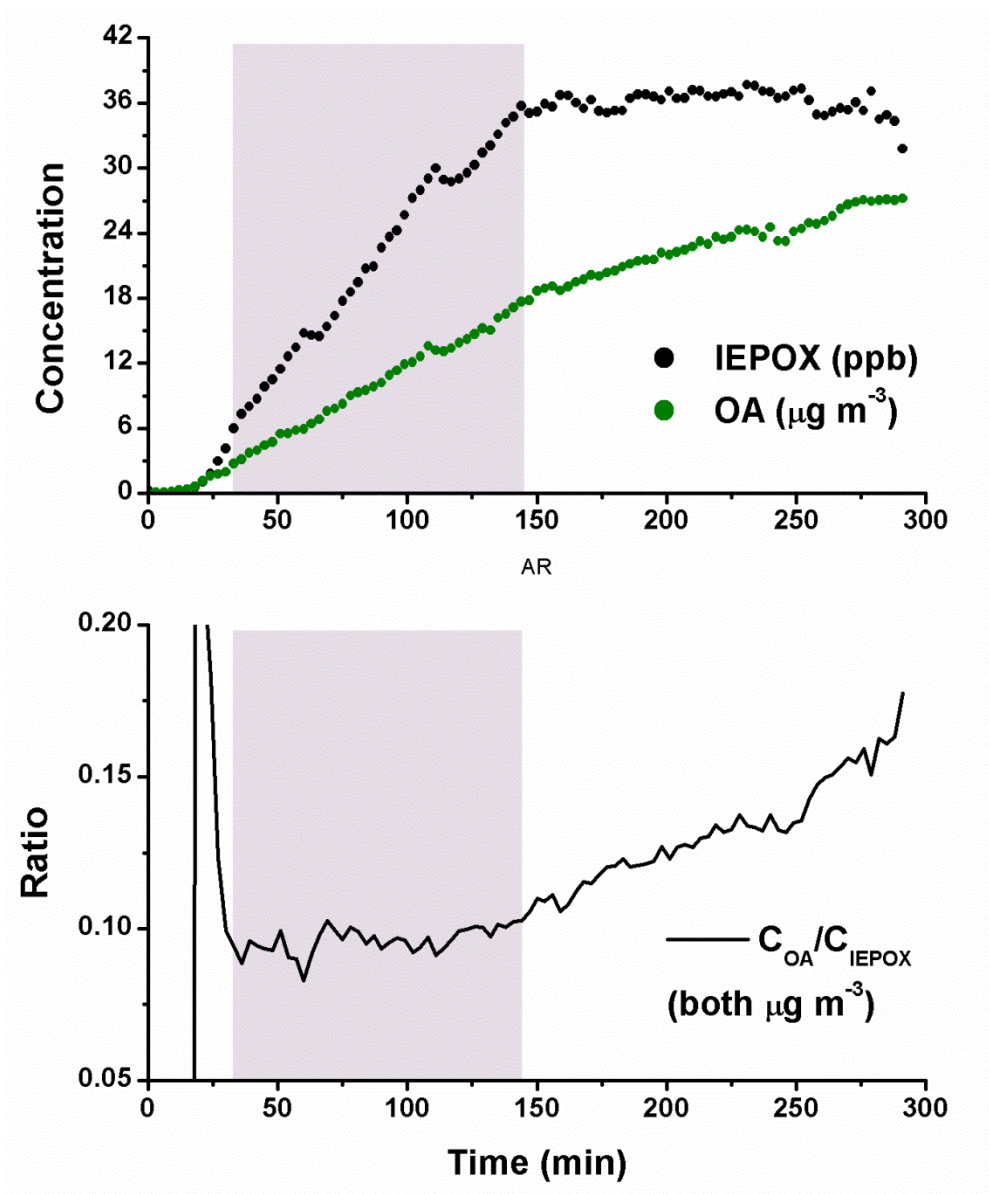

1 **Figure S2:** Vapor wall loss of *cis*  $\beta$ -IEPOX to the chamber walls.

2

3

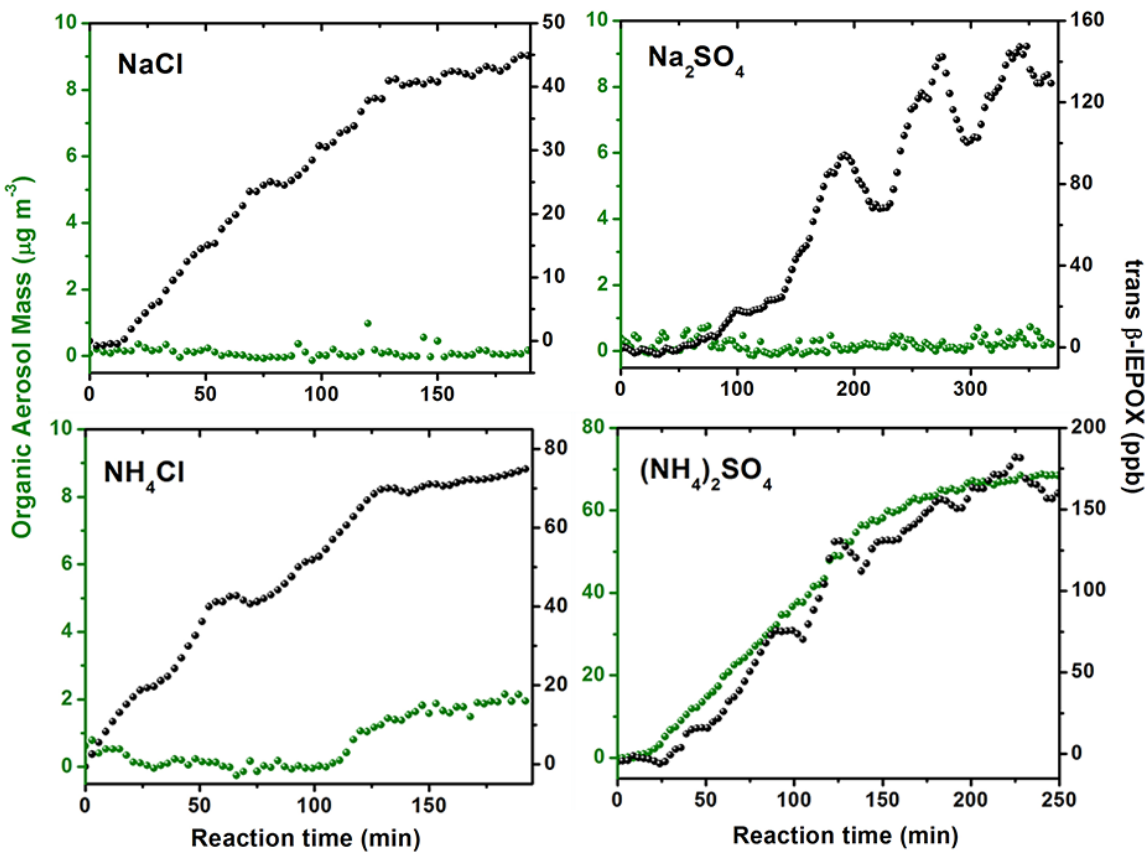

1 **Figure S3:** Top panel: OA grows in response to IEPOX gas-phase injection, but continues to  
2 grow after halting IEPOX injection, an indication that the system is not at equilibrium. Bottom  
3 panel: the ratio of the OA to gas-phase IEPOX starts off noisy and levels out as IEPOX is  
4 injected. The ratio continues to grow as gas-phase IEPOX stabilizes and OA continues to grow.  
5 The shaded panel where the ratio levels out is used in  $\Phi_{\text{OA/IEPOX}}$  calculations.

6

7

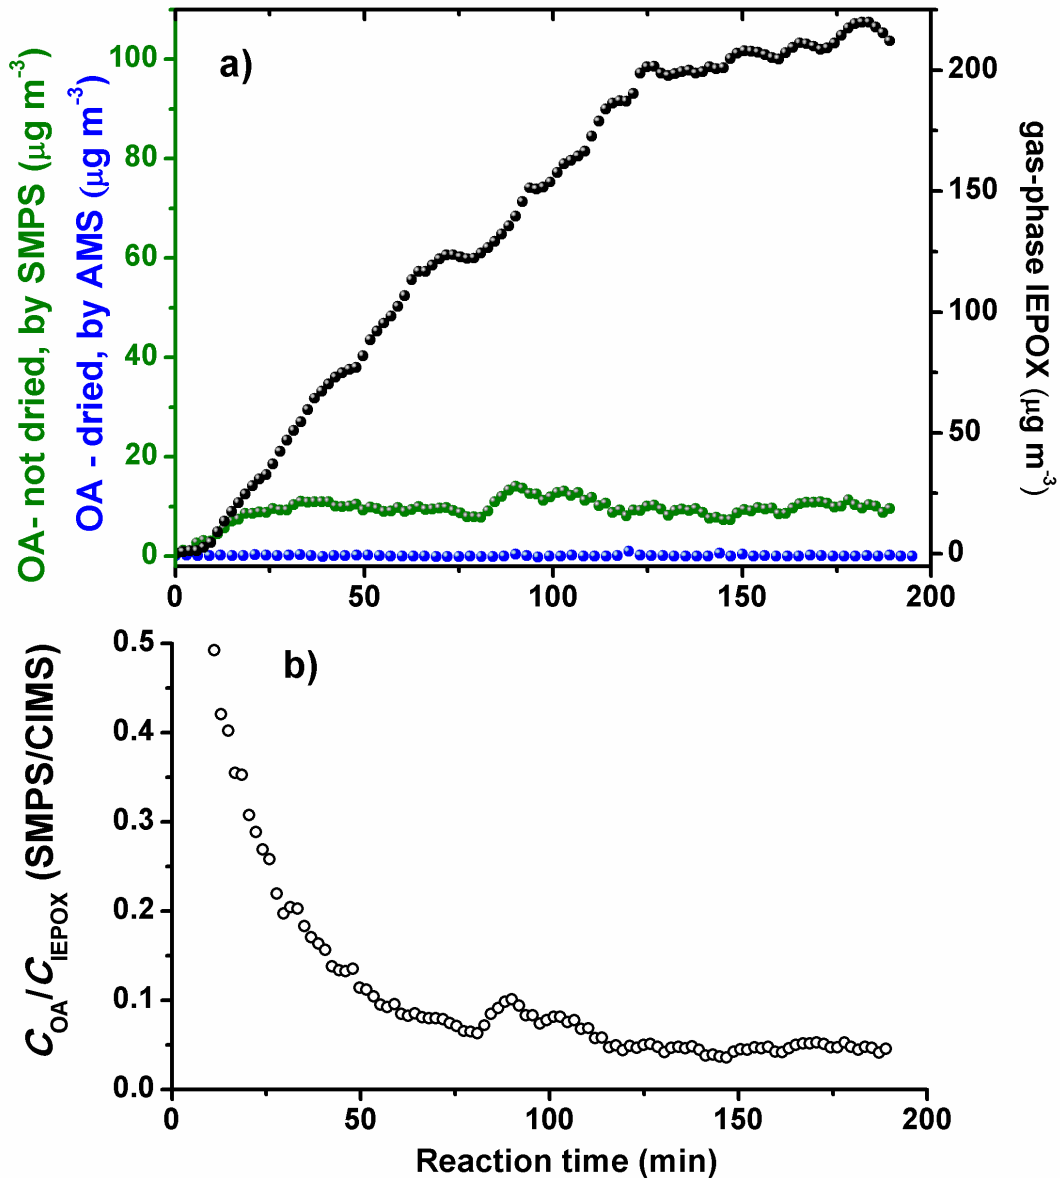

1 **Figure S4:** Typical behavior of the ratio of organic aerosol formed ( detected by AMS) to gas-  
2 phase IEPOX (detected by CIMS) during the course of an experiment.

3  
4  
5

1 **Figure S5:** SMPS data showed an increase in particle volume when gas-phase IEPOX is injected  
2 onto wet NaCl seeds, which stabilizes over the course of the experiment. ToF-AMS, which  
3 sampled dried particles, did not observe OA formation – an indication that the OA is reversibly-  
4 formed in the liquid water of NaCl seeds (equilibrium partitioning) and that the un-reacted  
5 IEPOX is removed from the particle phase upon drying.

6

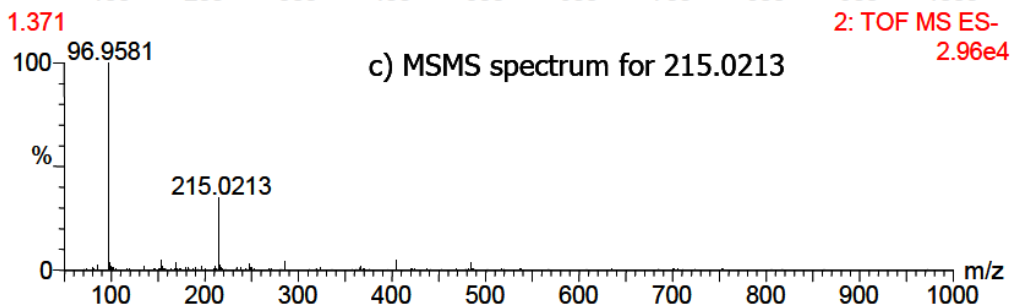

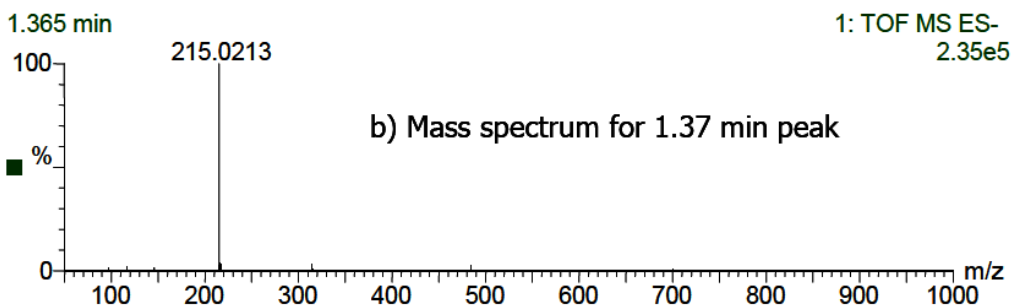

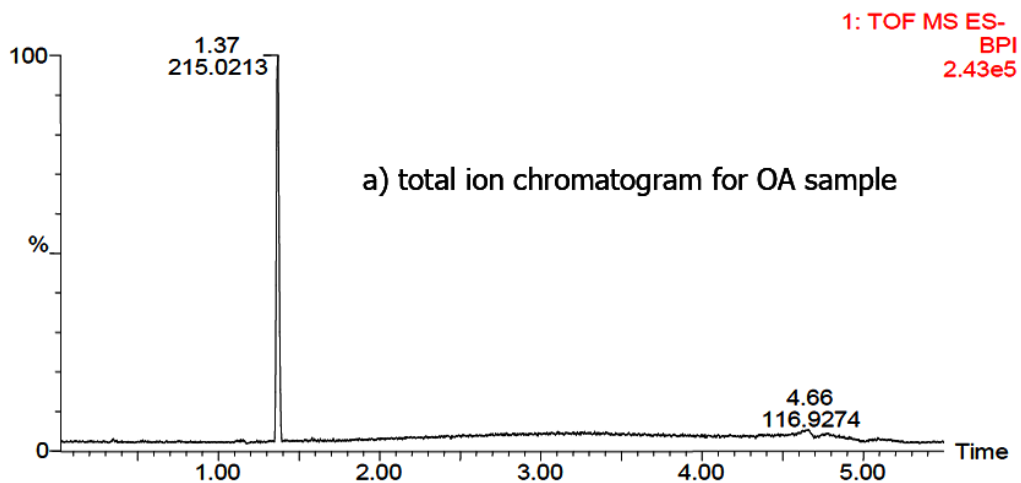

7

8

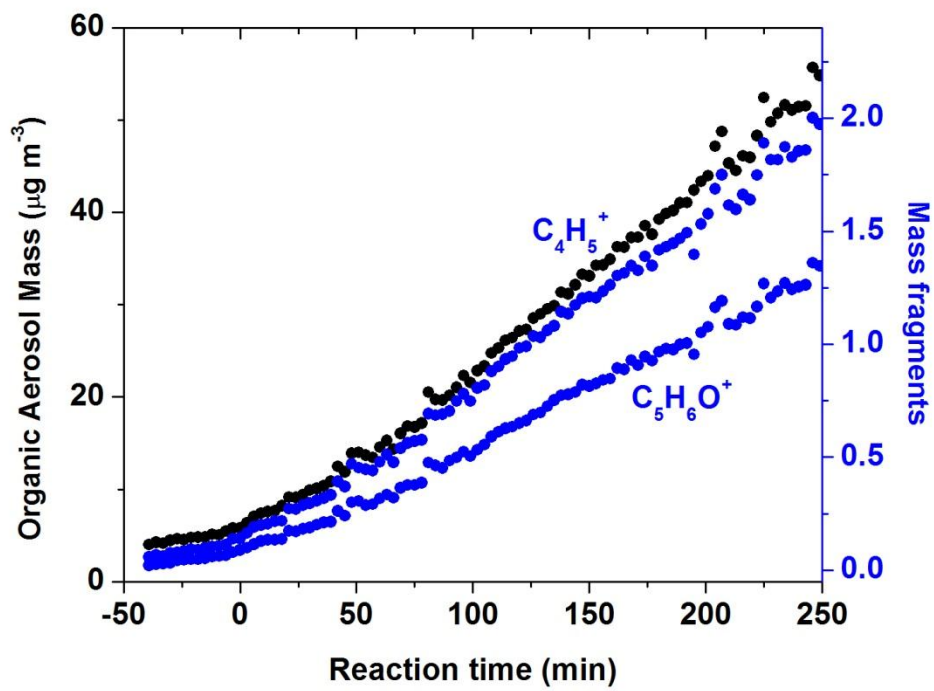

9

1 **Figure S6:** a) Total ion chromatogram for the IEPOX-derived OA collected onto a filter. The  
2 sharp peak at 1.36 minutes corresponds to the elution of the IEPOX-derived organosulfate. b)  
3 The mass spectrum corresponding to the 1.36 minute peak, showing that one peak ( $C_5H_{11}SO_7^-$ )  
4 dominates the spectrum. MSMS fragmentation (c) confirms organosulfates with the  $m/z$  96.9581  
5 ( $HSO_4^-$ ) product ion.
