1) hourly data, 2) available as integrated 24 h measurements, 3) available on IOP days

4) surface-based instrumentation collecting data through a system of solenoid valves in the balloon inlet package which allowed the measurements to cycle between tether sonde height levels (4 m, 33 m, 67 m, and 100 m) and provided a measurement at each level every 12 minutes.

+ The Air Quality Design, Inc chemiluminescence instrument is a two-channel, high performance NO detector that uses a remote-mounted inlet system which houses the catalytic and photolytic converters. The instrument was operated with one channel time-sharing between the NO and NO_x (NO+NO₂) measurements, and one channel continuously measuring the NO_y signal. The instrument was calibrated using a custom-built gas-phase titration calibration system that provided sensitivity measurements for both NO and NO₂ channels. In addition, the NO_y channel was periodically challenged with a permeation-tube based HNO₃ calibration source that was in place for calibration of the HNO₃ instrument to ensure that the NO_y converter was providing quantitative conversion of HNO₃. Standard addition calibration was used in all cases to ensure that the measured sensitivities were representative of the ambient sample matrix. The NO_{xy} remote inlet was mounted on the roof of the instrument enclosure at a height of about 3 m from the surface.

The HNO₃ measurement system was comprised of a commercial chemiluminescence NO detector with a remote mounted inlet system. The inlet system included a two-channel molybdenum catalytic NO_y converter, one of which also included a calcium carbonate coated denuder. The difference in signal between the two-channels represented the ambient [HNO₃]. The instrument was calibrated using the same NO, NO₂, HNO₃ calibration source utilized for the NO_{xy} instrument. The HNO₃ instrument inlet was co-located with the NO_{xy} inlet at 3 m above the surface.
