Supplement of

Aerosol indirect effects on the nighttime Arctic Ocean surface from thin, predominantly liquid clouds

Lauren M. Zamora et al.

Supplementary Notes on MOONLiT cloud selection criteria:

If the MOONLiT criteria were changed to include a) clouds with bases that were 200 m instead of 1 km above the surface, b) clouds above a separate ice cloud, or c) clouds below other non-opaque cloud layers (icy or otherwise), the MOONLiT cloud sample size would respectively have increased by 107 (121), 16 (28), and 303 (617)% over sea ice (open ocean). Any other differences between the MOONLiT cloud subset and the ONLi cloud subset was due to cases where uncertain aerosol CAD scores (<70) existed somewhere above or beneath cloud layer of interest. These clouds were allowed in the ONLi cloud subset, but not in the MOONLiT cloud subset.

Table S1. Median (interquartile range) and sample number (n) of Arctic Ocean ONLi cloud properties over sea ice, separated by altitude bins as classified by the criteria in Table 1 and by radar reflectivity above and below detection limit (DL, -29 dBZ). Red (grey) color indicates significant (not significant) differences compared to clean background clouds, as determined at 95% confidence using a permutation test.

^aAerosol-impacted, as determined in the third column of Table 1.

^bFor clouds with bases >750 m asl

^cPrecipitating clouds were included in this metric only.

Table S3: Median (interquartile range) of Arctic Ocean MOONLiT cloud properties as classified by the criteria in Table 1, separated by reflectivity above and below detection limit (DL, -29 dBZ) and surface regime. Red (grey) color indicates significant (not significant) differences compared to clean background clouds, as determined at 95% confidence using a permutation test. Blue indicates that significance was lost^c with altitude binning (relevant only to the open ocean cases).
