26 **Text SI-1. Description about the Study area**

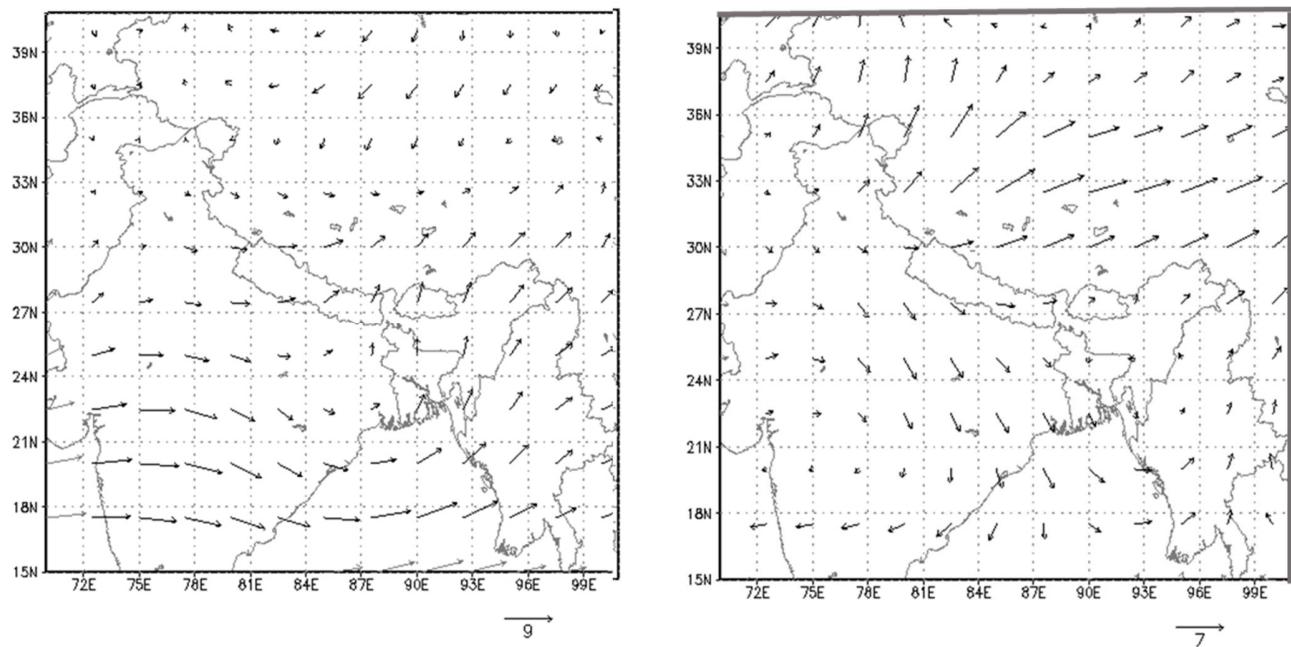

27

28 Kathmandu (1350m asl) located in mountain valley is the capital city of Nepal, with very dense
29 population (an area of 642 sq. km, population =2.5 million,). Agriculture, industry (instant food,
30 clothes, bricks), and tourism are the major economy of Kathmandu. Pokhara (750-1050m asl) is
31 second largest city after Kathmandu, covering an area of 225 sq. km with a population of 0.3 million.
32 Hetauda (100m) is relatively small with 135,475 populations. Different from Kathmandu, Pokhara
33 and Hetauda are agricultural cities, with large area of crop and vegetable production place and
34 market. Climate of these 3 cities are commonly influenced by the Indian monsoon in summer and
35 westerlies (south branch) in winter. Summer is warm and wet particularly in July-August but winter
36 is dry and cold. Among the cities, Hetauda is warmest followed by Pokhara and Kathmandu,
37 whereas annual rainfall follows the order Pokhara (~3900mm)>Hetauda (~2250mm)> Kathmandu
38 (1450mm).

69 **Text SI-2. Chemical cleanup procedure**

70

71 Each extract was concentrated using rotary evaporator and solvent exchanged to hexane. The concentrated
 72 extract was loaded on the top of a chromatography column (from the top to bottom: 1 cm of anhydrous
 73 Na₂SO₄, 2g activated alumina, and 3g activated silica gel), and eluted with 30 mL mixture of DCM and
 74 hexane (1:1). The volume of eluate was reduced under gentle stream of high purity nitrogen to about 1ml
 75 and added 20µl internal standard containing a known quantity of pentachloronitrobenzene (PCNB) and
 76 decachlorobiphenyl (PCB-209). Finally, the volume was reduced to 100 µl under gentle stream of nitrogen
 77 before analysis.

78 **Text SI-3. Details about the gas chromatography temperature program**

79

80 Helium was used as the carrier gas at 1 mL min⁻¹ under constant-flow mode. The oven temperature began
 81 at 100 °C for 2 min, ramped up at a rate of 20°C min⁻¹ to 140°C, at 4°C min⁻¹ to 200°C (10 min hold time),
 82 then at 4°C min⁻¹ to 310°C and held for 5 min.

86 *MDL Method detection limit

87 **Text SI-4. Details about PUF-disk and Sampling rate**88 **a. Sample holder and sampler**89 **Dimensions of PUF-Disks:**

90 Polyurethane foam disk used for air sampling had the following dimensions: Diameter (d) = 135.5
 91 cm, thickness (h) = 1.3 cm; mass (m) = 3.78 g; area (A) = 341.4 cm² (ND34 m²); Volume (V) =
 92 186.1 cm³ (ND00186 m³); Density (δ) = 20305.6 g/m³.

93 A chamber to house the PUF-disk was prepared connecting two stainless steel bowls by means of
 94 hinges and a lock. It was so designed that it would protect the PUF-disk from direct precipitation,
 95 sunlight and course particle deposition and allow ambient air to pass through chamber from the
 96 gap between bowls and small holes at the base of bottom bowl. This design of chamber has been
 97 successfully calibrated and used in numerous previous studies (Shoeib & Harner, 2002a; Harner et
 98 al., 2004; Pozo et al., 2006; Harner et al., 2006). PUF disks samplers were pre-cleaned by Soxhlet
 99 extraction using dichloromethane (DCM) for 24 h and dried for 24h in a clean desiccator under
 100 reduced pressure. Before sending for field deployment, the PUF-disks were spiked with four
 101 performance reference compounds (PRCs, PCB-30, -54, -104, -188), that were used to determine
 102 the site-specific sampling rates (Pozo et al., 2009). After applying DCs, each PUF-disks was
 103 wrapped with clean aluminum foil packed into a plastic bag and stored in a tin container. Five field
 104 blanks for Kathmandu, 3 for Pokhara and 3 for Hetauda were prepared to inspect the possible
 105 contamination during handling, storage, and transport.

106 **b. Calculation of Sampling Rate “R”**

107 To assess the site specific sampling rates, PRCs were added to each PUF disks prior to their
 108 deployment. Loss of DCs during sampling period was quantified based on individual recoveries.
 109 Ideally, recoveries between 20 and 80% of their initial amount would indicate the linear sampling
 110 of individual PAS. This requires DCs with a wide range of octanol-air partition coefficients (K_{OA}).
 111 By measuring the loss of DCs during sampling period site-specific air sampling rate ‘R’ can be
 112 estimated using the following relationship given by Moeckel et al., (2009)

$$113 R = \frac{-\ln\left(\frac{C_{DC}^{corr}}{C_{DC,0}}\right) \cdot K_{PAS-A} \cdot \rho_{PAS} \cdot V}{t} \quad (1)$$

$$115 \text{With } C_{DC}^{corr} = \frac{C_{DC}}{\frac{C_{DC-stable}}{C_{DC-stable,0}}}$$

$$116 \quad 117 \quad 118 \quad K_{PAS-A} = 10^{0.6366 \log K_{OA} - 3.1774} \quad (2)$$

119 Where C_{DC} and $C_{DC-stable}$ are the concentrations of DC and DC-stable at the end of the deployment
 120 period, respectively (ng sample⁻¹). K_{PAS-A} is the chemical’s PAS-air partition coefficient with units
 121 of m³ g⁻¹ and it can be calculated according to the regression (eq 2) given by Shoeib and Harner,
 122 (2002), ρ_{PAS} is the PAS bulk density (g m⁻³), V is the volume of the PAS (m³), and t is the
 123 deployment period in days. PCB-188 is used as DC-stable for correcting the losses of DCs. Only
 124 DCs that have recoveries within the desired range of between 20% and 80% should be used to
 125 estimate uptake rates.

221

222

223

Figure SI-12. Seasonal variation of HCB in 3 cities of Nepal

224 **Text SI-5. Estimation of loss rate of atmospheric OCPs**

225

226 In the equation,

227
$$\tau_a = \frac{\ln 2}{k_{degr} + k_{wet} + k_{dry}} \quad (1)$$

228 Where τ_a is atmospheric residence time,

229 k_{degr} is photochemical degradation rate in air (s^{-1})

230 k_{wet} wet deposition rate (s^{-1})

231 k_{dry} dry deposition rate(s^{-1})

232 In general, degradation due to OH is considered the dominant process and Bayer et al., 2003 derived a simple
233 temperature dependent relation to estimate OH concentration i.e. [OH] in atmosphere.

234
$$[OH] = 0.5 + 0.4(T - 273.15) \times 10^5 \quad (2)$$

235 where T is absolute temperature (K)

236 Then, using the rate constant K_{OH} (Table SI-12) the degradation rate k_{degr} is estimated as,

237
$$k_{degr} = K_{OH}[OH] \quad (3)$$

238 Assuming the gas phase as dominant form of the pollutants in the atmosphere wet deposition has been estimated using
239 the relation

240
$$k_{wet} = \frac{R_i W_G}{h} \quad (4)$$

241 Where R_i = annual rain intensity (mm a⁻¹)

242 W_G = gas phase scavenging ratio

243 h = atmospheric boundary layer height (m) and

244 effective gas phase scavenging ratio is estimated as reciprocal of Henry law coefficient

245
$$W_G = \frac{RT}{H} \quad (5)$$

246 where R = Gas law constant (8.314 Pa m³mol⁻¹K⁻¹)

247 T = absolute temperature (K)

248 H = Henry's law constant

249 For dry deposition rate the k_{dry} , has been estimated as

250
$$k_{dry} = \frac{V_D}{h} \quad (6)$$

251 Where V_D is dry deposition velocity (cm s⁻¹)

257 Temperature dependent dry deposition velocity for the gas phase pollutants can be estimated using relation
258 proposed by González-Gaya et al., 2014

259
$$\log V_D = -0.261 \log PL - 2.670 \text{ cm s}^{-1}$$

260

261 **Table SI-12. Temperature dependent Henry's law constant and vapor pressure with Rate constant**
262 **of hydroxyl radical reaction at 25°C**

263

Compounds	$\log H (\text{Pa m}^3 \text{ mol}^{-1})$	$\log PL (\text{Pa})$	$K_{OH} (25^\circ\text{C}) \text{ cm}^3 \text{ molec}^{-1} \text{ s}^{-1}$
p, p'-DDT	13.02-3369/T	13.02-4865/T	1.5×10^{-12}
α -HCH	8.98-1714/T	11.12 – 3497/T	1.4×10^{-13}
γ -HCH	11.58-3049/T	11.98-3905/T	1.9×10^{-13}
HCB	11.6-3013/T	11.11-3582/T	2.7×10^{-14}

264

265 Parameters about Henry's law constants, OH initiated atmospheric reaction rate and chemical's property data are
266 found from literatures (Passivirta et al., 1999; Hinckley et al., 1990; Bai et al., 2013; Xiao et al., 2004; Brubaker et
267 al., 1998; Jautunen et al., 2006)

276

277

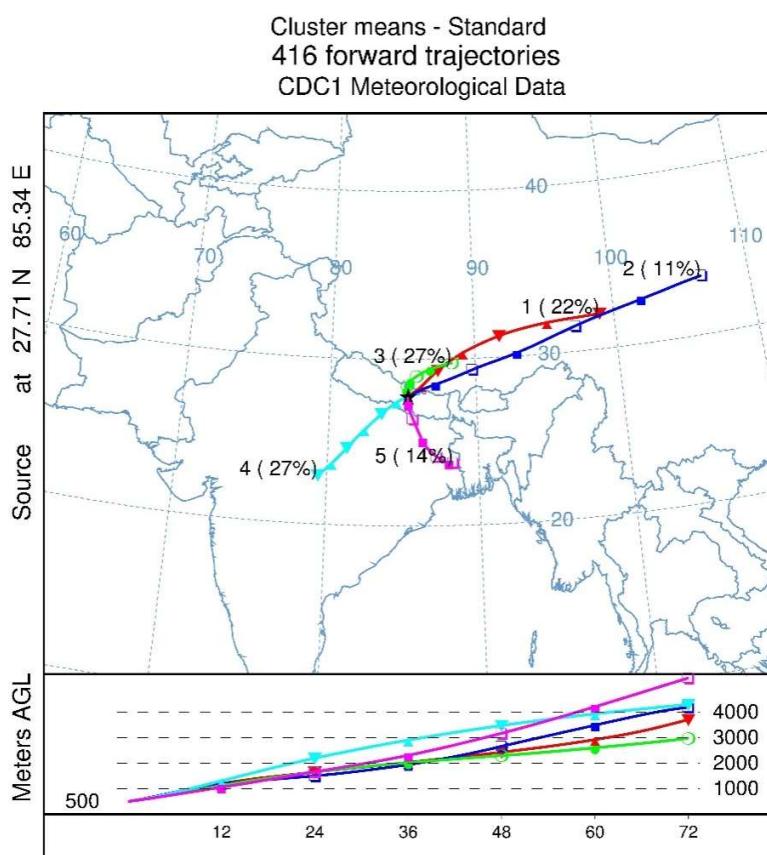

278 **Text SI-6 Uncertainties of CTD**

279 Given soil can absorb atmospheric POPs, it may retard the transport of POPs. Previous study had
280 investigated the air-soil exchange of POPs along south slope of Nepal Himalaya mountain, and the
281 results found volatile compounds such as HCB, PCBs and HCHs reached air-soil exchange equilibrium
282 in low elevation cities (Gong et al., 2014). This means for the volatile compounds, only the atmospheric
283 processes (i.e. OH degradation and dry/wet deposition) are major loss process. Due to the possible
284 overestimation of OH concentration reported by Anderson et al. (1996), τ_a will be underestimated and
285 then CTD will be underestimated. With respect to less volatile compounds such as DDTs, their air-soil
286 exchange showed deposition trend (Gong et al., 2014), suggesting soil absorption should not be
287 ignored. As this will reduced τ_a of DDTs, and lead to the overestimation of CTD.

288

289 **Text SI-7 Generation of forward trajectories**

290 NOAA's HYSPLIT model and the NCEP/NCAR Global Reanalysis data set for Kathmandu were used
291 to calculate forward trajectories. Forward trajectories were traced for 3 days at 6 h intervals at 100 m
292 above sea level. All 416 trajectories were grouped into 5 clusters. Sixty present of trajectories (sum of
293 cluster 1, 2 and 3) move northward, crossing the Himalaya and reaching southeastern Tibetan Plateau.

294

295 **Figure SI-13. Clusters of forward trajectories for Kathmandu**
