Supplement of

Intra-regional transport of black carbon between the south edge of the North China Plain and central China during winter haze episodes

Text S1 Description of CWT

To distinguish the pollution levels of different potential regions, a concentration-weighted-trajectory (CWT) model was employed in this study. The CWT was calculated according to:

$$C_{ij} = \frac{1}{\sum_{l=1}^M \tau_{ijl}} \sum_{l=1}^N C_l \tau_{ijl} \quad (1)$$

where C_{ij} represents the average weight concentrations in the grid cell (i, j) ; C_l is the measured BC concentration observed on the arrival of trajectory l ; τ_{ijl} is the number of trajectory end points in the grid cell (i, j) associated with the C_l sample.

In order to consider only air parcels with good representativeness, a weighing function was added to the calculation to down weight cells associated with low values of n . The default weighting function was used as below:

$$W = \begin{cases} 1.00 & \text{for } \log(n + 1) \geq 0.85 * \max_{\log(n+1)} \\ 0.725 & \text{for } 0.60 * \max_{\log(n+1)} > \log(n + 1) \geq 0.85 * \max_{\log(n+1)} \\ 0.475 & \text{for } 0.35 * \max_{\log(n+1)} > \log(n + 1) \geq 0.60 * \max_{\log(n+1)} \\ 0.175 & \text{for } \log(n + 1) < 0.35 * \max_{\log(n+1)} \end{cases} \quad (2)$$

Table S1 Reported BC levels in China and around the world.

Table S3 Differences of meteorological conditions (temperature (T), relative humidity (RH), pressure (P), visibility (Vis), and boundary layer height (BLH)) at the five observation sites.

Pink color means that the difference between the two variables was significant at 0.05 level; yellow color means that the difference between two variables was not significant ($p > 0.05$).

Table S4 Number of data for the different air quality in Figure 4.

| | HA | LH | SX | WH | XY |
|-----------------|-------|-------|-------|------|-------|
| Clean | 17424 | 7629 | 10500 | 1983 | 2315 |
| Light pollution | 7650 | 14303 | 9720 | 1632 | 13334 |
| Heavy pollution | / | 2313 | / | / | 2856 |

/: no heavy pollution episode existed.

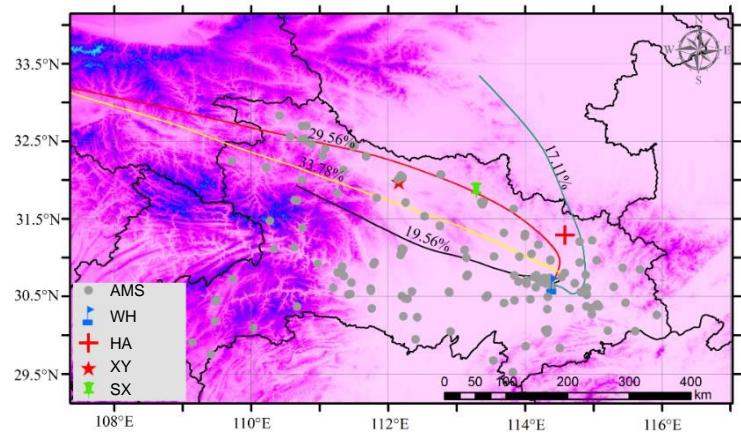

Figure S1 Cluster analysis results of air masses transported to Wuhan in January 2017. (AMS, WH, HA, XY, HA stand for ambient air monitor station site, Wuhan, Hong'an, Xiangyang, and Suixian, respectively)

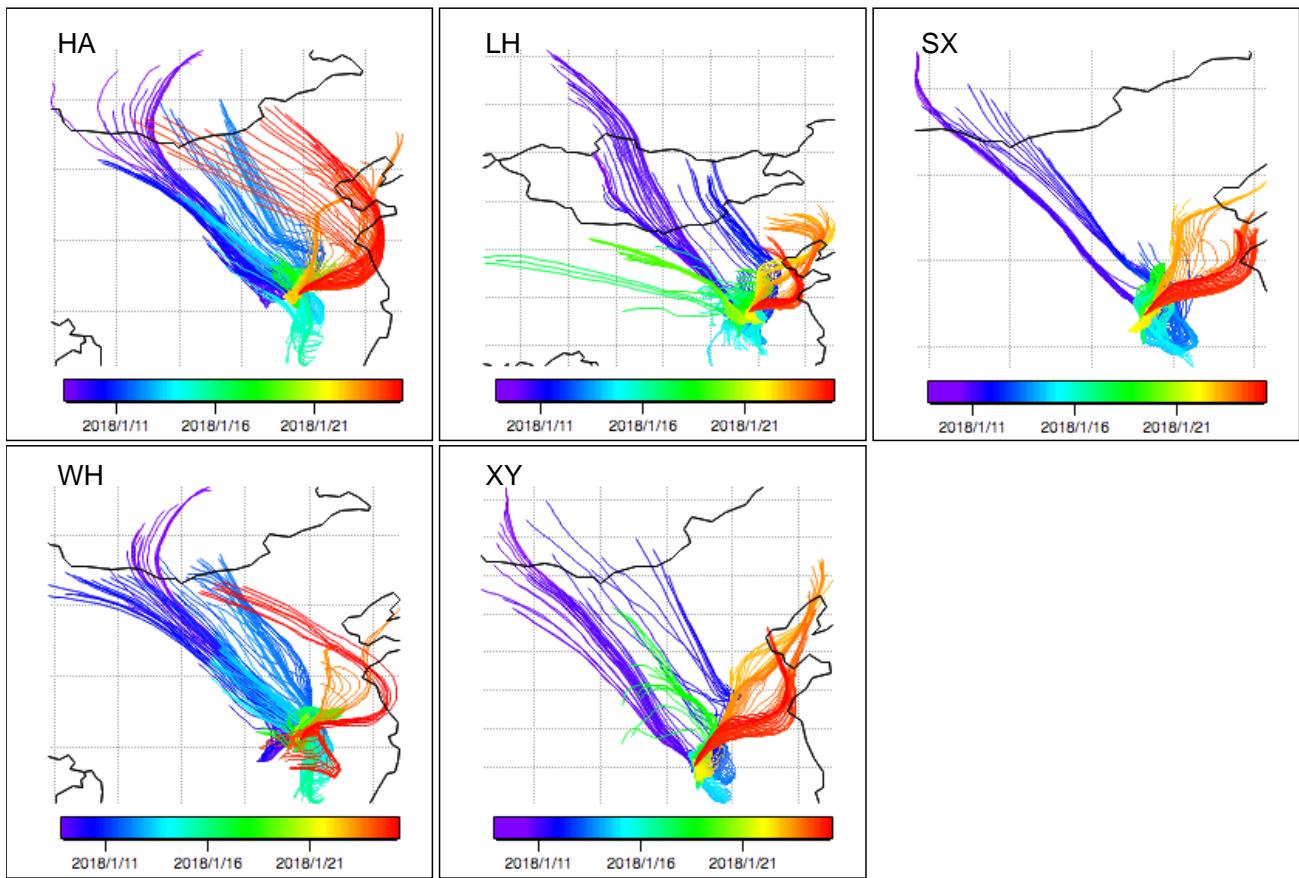

Figure S2 Hourly trajectories reaching at the five sites during the observation period.

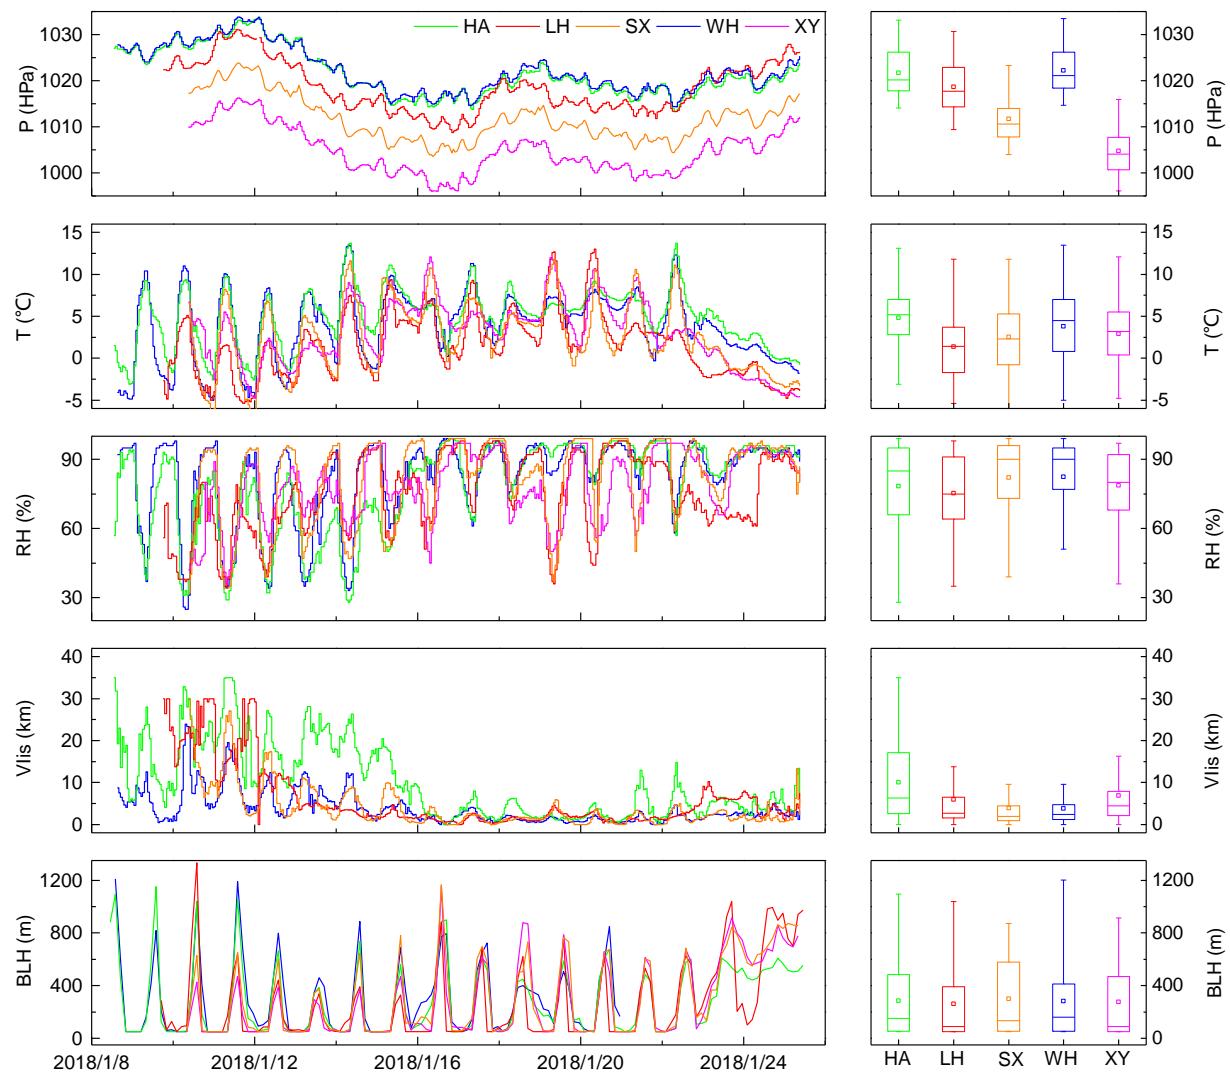

Figure S3 Time series and box plots of meteorological parameters including pressure (P), temperature (T), relative humidity (RH), visibility (Vis), and boundary layer height (BLH) at the five sites.

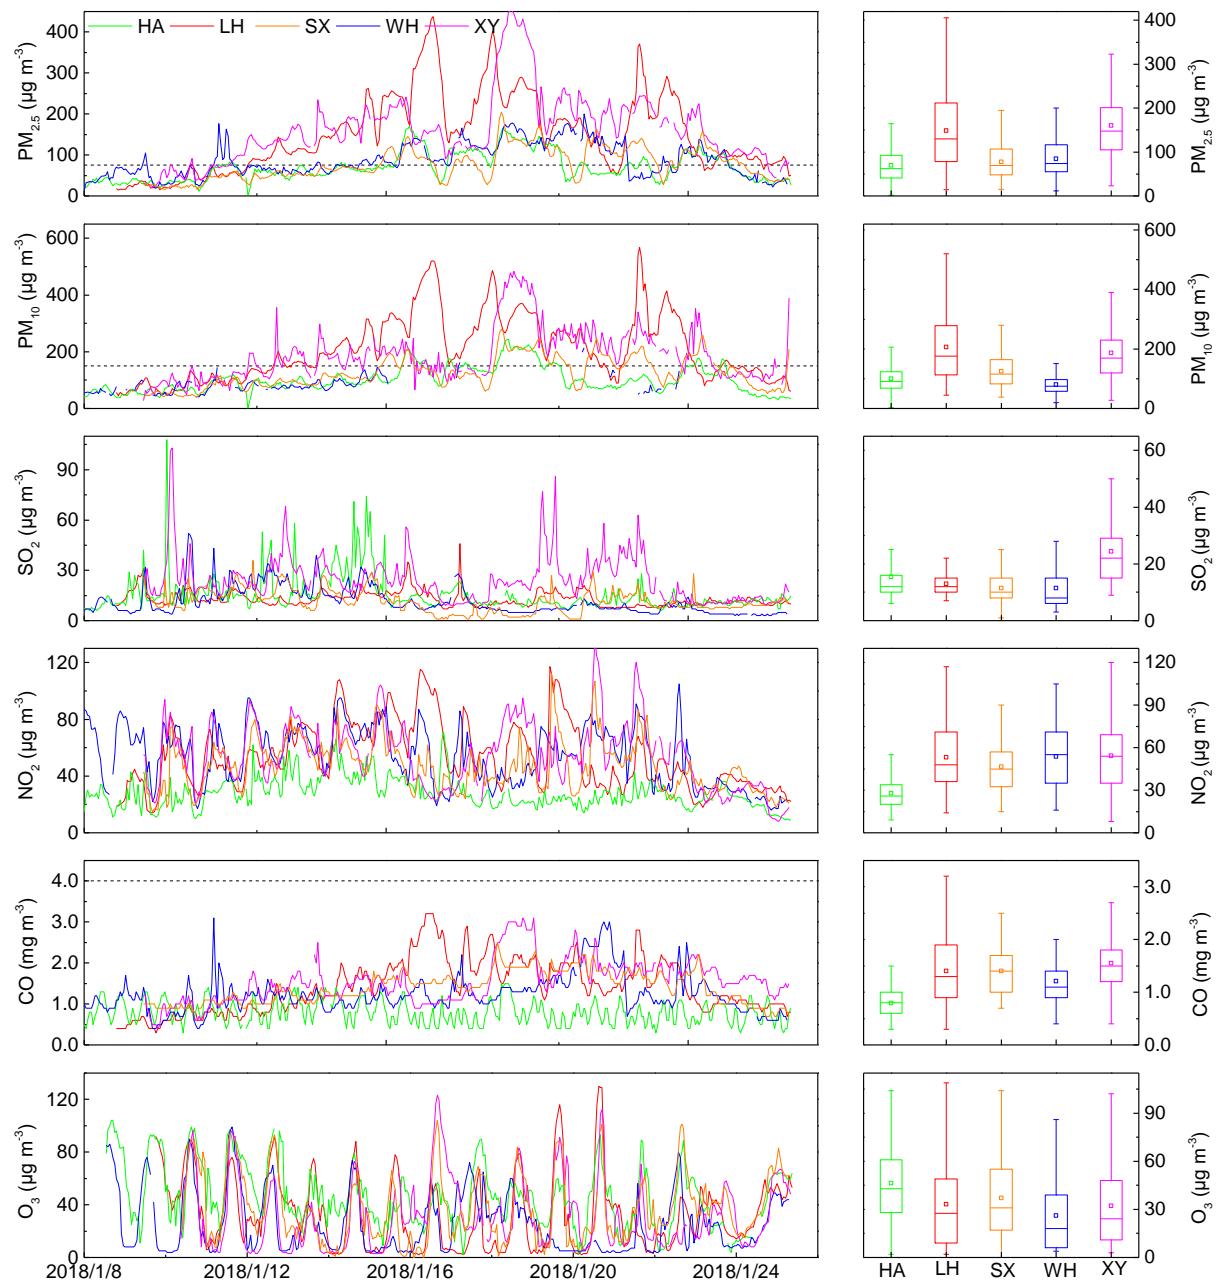

Figure S4 Time series and box plots of the hourly averaged PM_{2.5}, PM₁₀, SO₂, NO₂, CO, and O₃ concentrations at the five sites for the observation period (2018/1/8~2018/1/25). The dash lines are the corresponding daily secondary standards of the ambient air quality in China (GB3095–2012). The SO₂, CO and O₃ concentrations were lower than their secondary standards (150 $\mu\text{g m}^{-3}$ for SO₂, 4 mg m^{-3} for CO, and 160 $\mu\text{g m}^{-3}$ for O₃) during the entire periods.

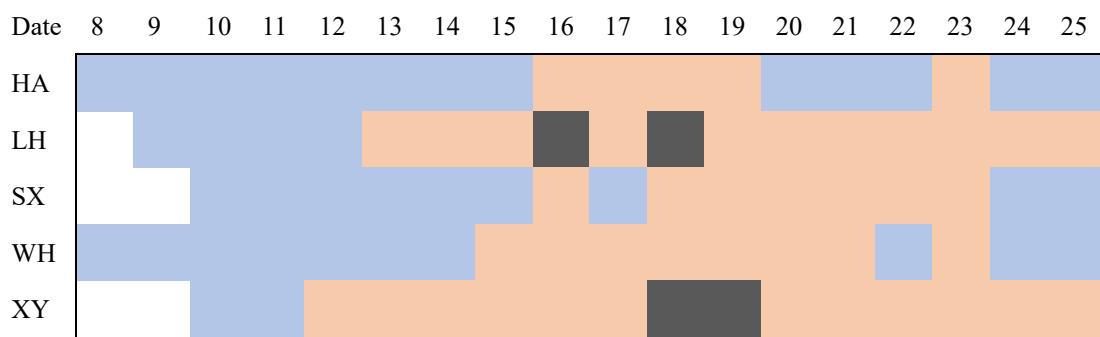

Figure S5 Daily air quality of each site during the observation periods. The blue, orange and dark stand for good ($\text{PM}_{2.5} < 75 \mu\text{g m}^{-3}$), light polluted ($75 < \text{PM}_{2.5} < 250 \mu\text{g m}^{-3}$) and heavily polluted ($\text{PM}_{2.5} > 250 \mu\text{g m}^{-3}$) air quality, respectively.

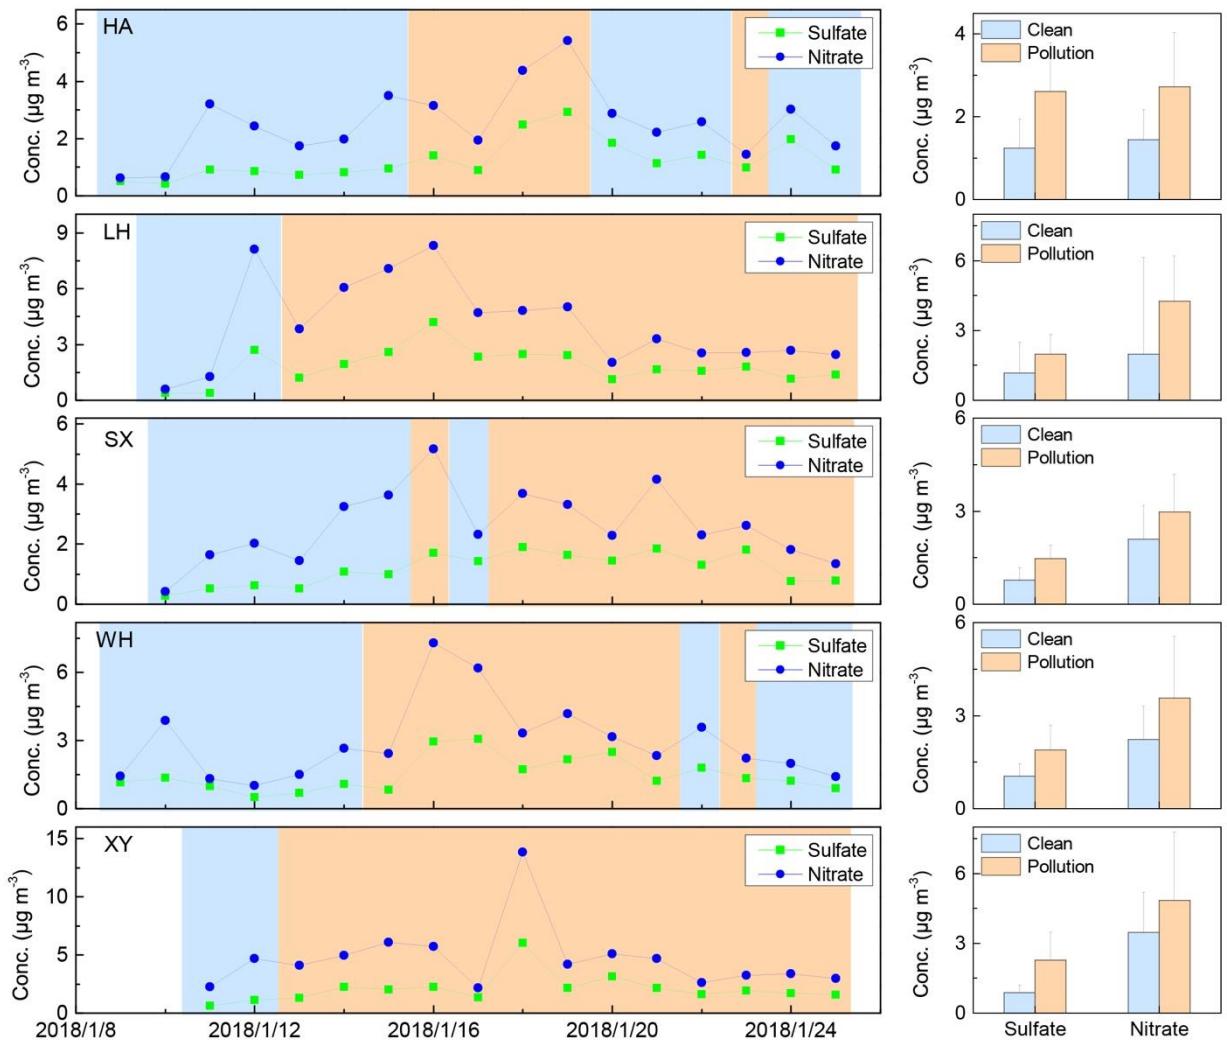

Figure S6 Daily concentrations of sulfate (green line) and nitrate (blue line) during observation (left panel) and their average concentrations for clean days (blue) and pollution episodes (orange) (right panel).

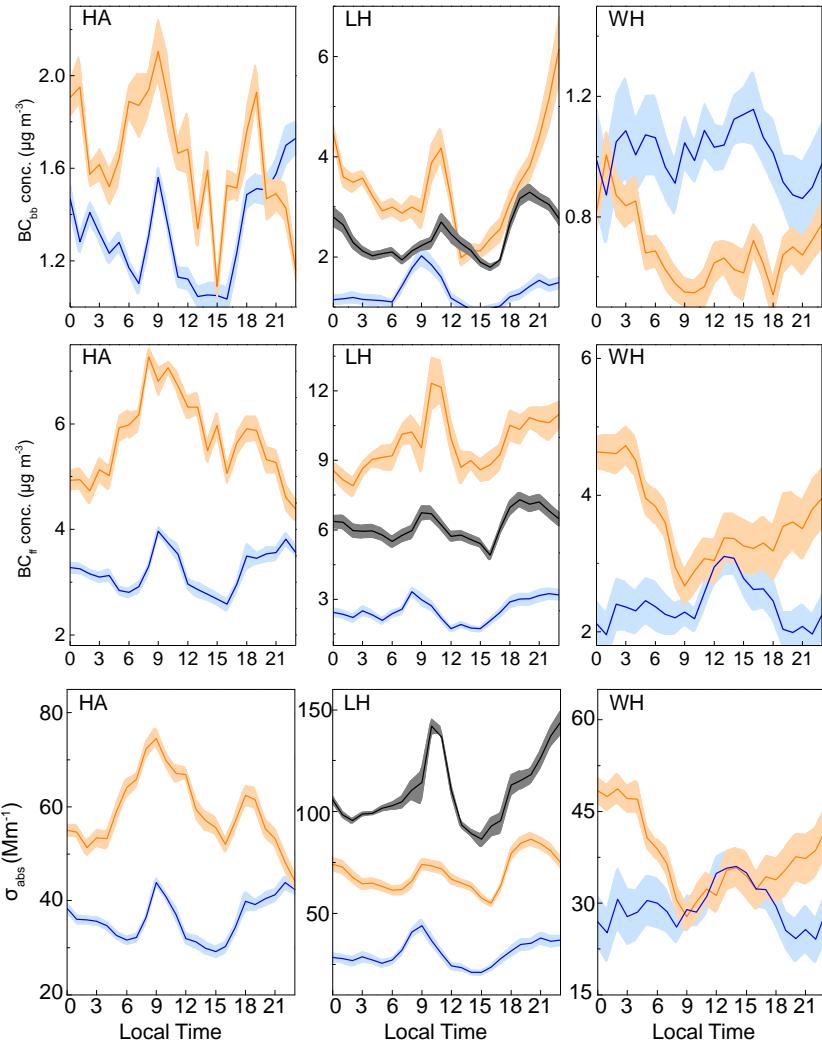

Figure S7 Diurnal variations of BC_{bb} (up panel) and BC_{ff} (bottom panel) at HA, LH and WH under different air quality.

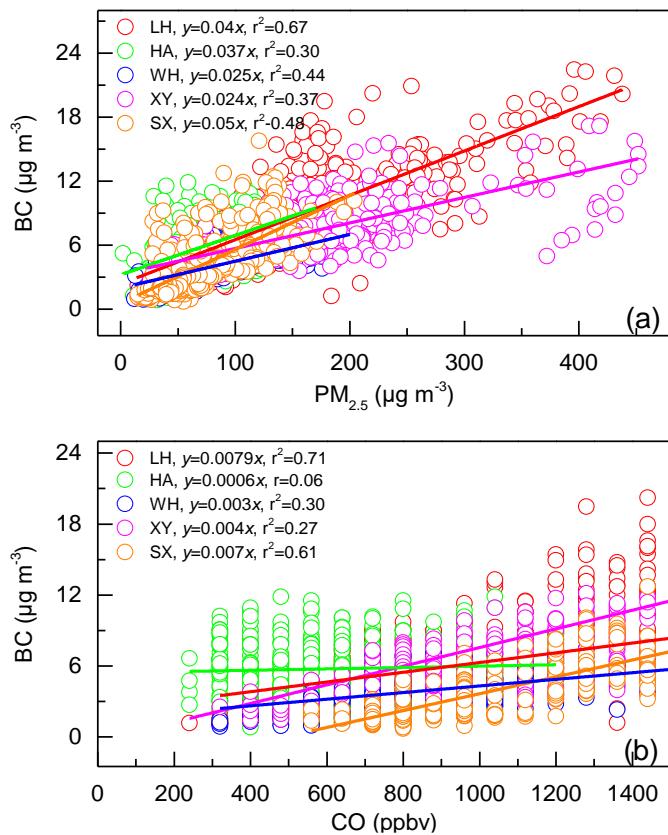

Figure S8 Scatter plots of BC vs PM_{2.5} (a) and BC vs CO (b).

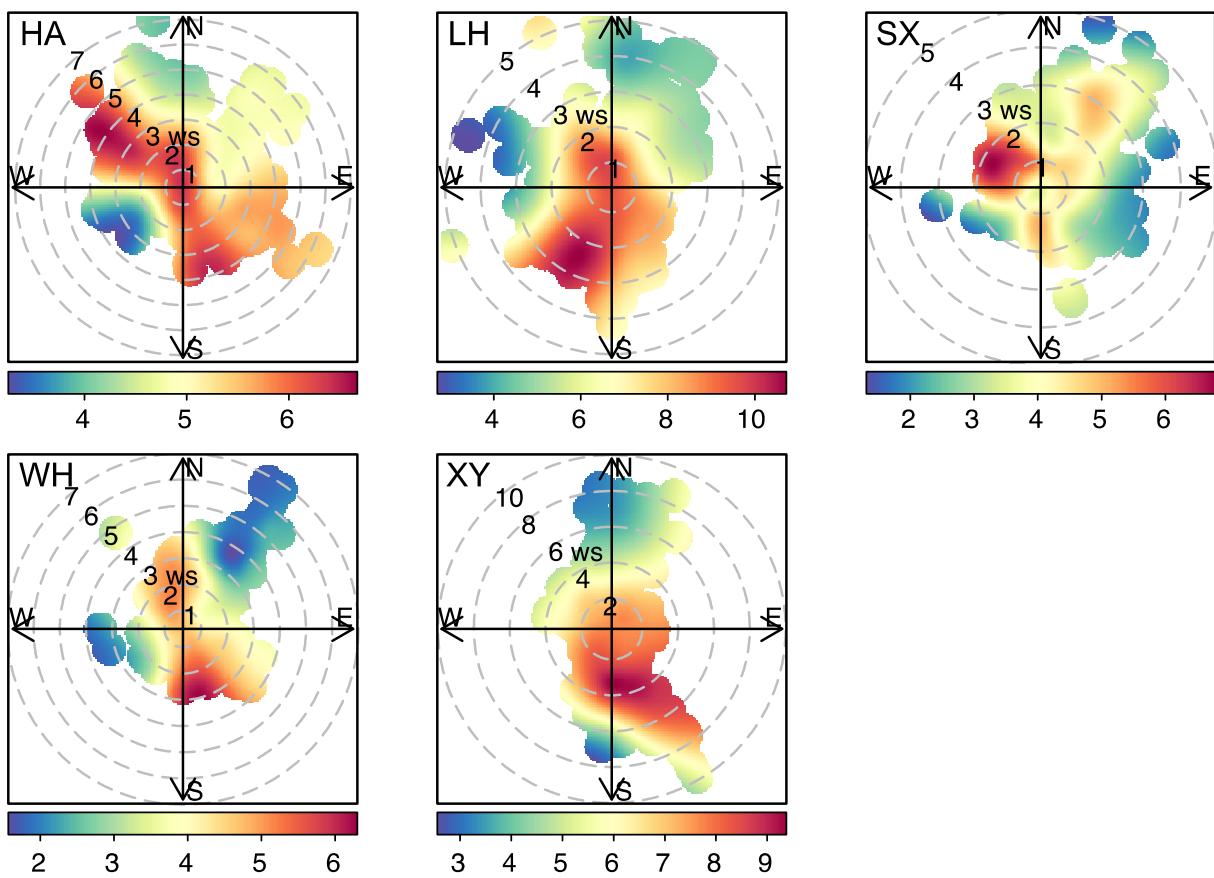

Figure S9 Conditional bivariate probability function plots of eBC ($\mu\text{g m}^{-3}$) at the five observation sites.

Figure S10 Locations of the fire spots downloaded from MODIS during the observation period (2018/1/08~2018/1/25).

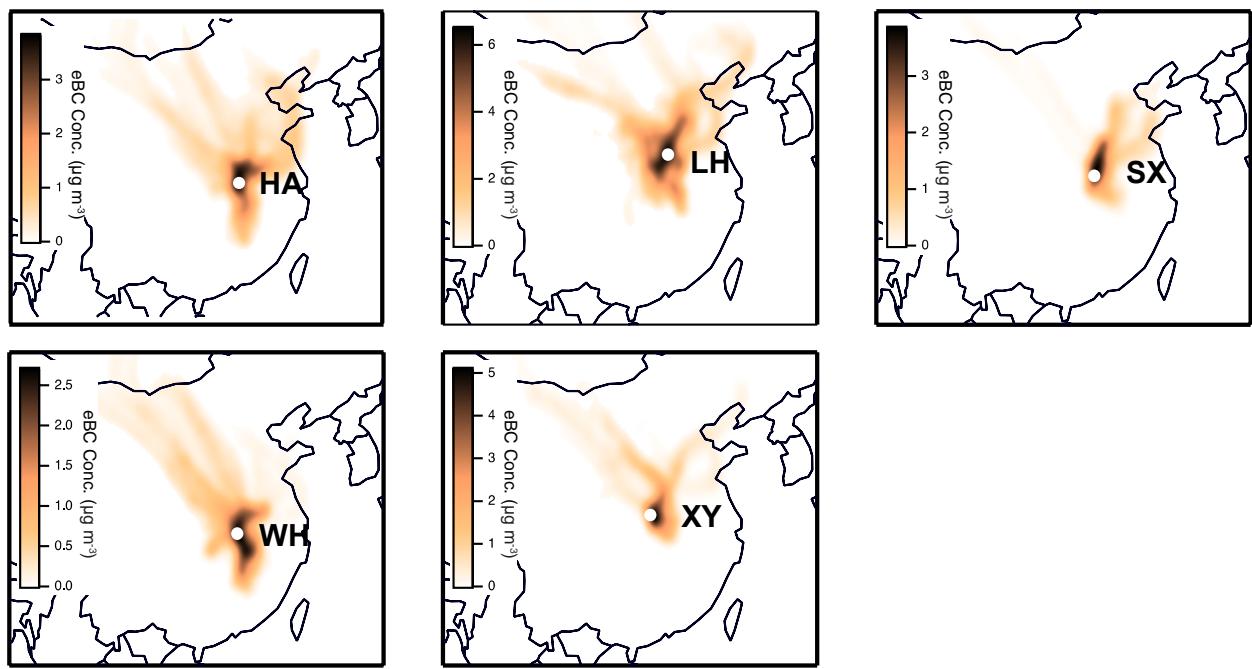

Figure S11 CWT results of eBC at the five sites during the observation period
