44 scattering coefficient at the three sites

45 Figure S11. Hygroscopic growth curve of $\text{PM}_{2.5}$ at NJU.

46 Figure S12. The correlation between the scattering coefficients estimated by $f(\text{RH})$
47 and those simulated with Mie theory under the ambient conditions.

48 Figure S13. The comparison of the observed scattering coefficients and those
49 estimated with the external, internal, core-shell mixture assumption under the ambient
50 condition at NJU.

51 Figure S14. The box plots of the ratios of light absorption BrC mass to the total BrC
52 mass under the three pollution levels. The box plots indicate the mean concentration
53 (square symbols) and the maximum, 99th, 75th, 50th, 25th, 1st percentiles, and
54 minimum.

55 Figure S15. The source profiles for accumulation mode particles from the PMF model
56 at NJU (a), PAES (b) and NUIST (c).

S1. IMPROVE1999 and IMPROVE2007 algorithms

The PM_{2.5} scattering coefficient could be calculated with two IMPROVE algorithms, as described in Pitchford et al. (2007). Briefly, the IMPROVE1999 and IMPROVE2007 algorithms are expressed with Eqs. (S1) and (S2), respectively:

$$b_{sca} \approx 3 \times f(RH)[Sulfate] + 3 \times f(RH)[Nitrate] + 4 \times [Organic Mass] + 1 \times [Fine soil] \quad (S1)$$

$$b_{sca} \approx 2.2 \times f_s(RH)[Small Sulfate] + 4.8 \times f_L(RH)[Large Sulfate] + 2.4 \times f_s(RH)[Small Nitrate] + 5.1 \times f_L(RH)[Large Nitrate] + 2.8 \times [Small Organic Mass] + 6.1 \times [Large Organic Mass] + 1 \times [Fine soil] + 1.7 \times f_{ss}(RH)[Sea salt] \quad (S2)$$

The four major components in Eq. (S1) are sulfate (assumed to be (NH₄)₂SO₄), nitrate (assumed to be NH₄NO₃), organic mass (assumed to be organic compounds), and fine soil (crustal elements plus oxides). The PM_{2.5} scattering coefficient can be thus estimated by multiplying the concentrations of the four chemical components by typical component-specific mass scattering efficiencies. $f(RH)$ denotes the water growth terms for sulfate and nitrate.

IMPROVE2007 separates the large and small particle modes for sulfate, nitrate and OM using a simple mixing model, and different mass scattering efficiencies are used for the two modes (Eq. (S2)). With an assumption of log-normal mass size distribution, the large and small modes are described by the D_g and geometric standard deviations (σ_g) at 0.5 μm and 1.5, and 0.2 μm and 2.2, respectively. Empirically, the fraction of each particle component in the large mode can be calculated by dividing the total concentration of the component by 20 μg/m³. If the concentration is above 20 μg/m³, all the mass is considered to be in the large mode. A sea salt term is added as a particular concern for coastal monitoring sites. The water growth curves for sea salt and the large and small particle modes of sulfate and nitrate can be referred to Pitchford et al. (2007).
