MD: Models and Datasets supplement

This supplement includes additional information about the MODIS-DOD product, following the reference [1], and figures that compares this product with other MODIS based products and IASI. It also have detailed information about ESM-CRESCENDO models properties of mineral dust. Includes the dataset compiled of mineral total dust deposition flux and two tables that summarize the information used from LISA datasets over Sahel. It complements the datasets and model sections of the main paper: *Evaluation of natural aerosols in CRESCENDO-ESMs: Mineral Dust*.

Datasets

Datasets: Satellite Retrievals

IASI dust optical depth

The Infrared Atmospheric Sounder Interferometer (IASI) is a Fourier spectrometer onboard MetOp-A. In contrast with the MISR and MODIS whose measures are focused in the visible, IASI measures in the infrared. We used the IASI dust optical depth product derived from the IASI $10\mu\text{m}$ AOD. Because dust is mostly composed of particles in the coarse-size mode its spectral response cover also infrared channels. The IASI measurements cover altitudes that are considerably higher than the first hundred meters over the ocean where most of the mass of sea-salt aerosols resides. Therefore it is possible to ascertain dust coarse optical depth [2] from IASI $10\mu\text{m}$ AOD. The dataset covers the time-interval Jul-2007 to Dec-2014. Because IASI gives an estimation of dust optical depth at infrared, but not at 550 nm like model diagnostic. The figure S.MD.3 compares this product with MODIS DOD products. Note that it is possible to reconstruct a confidence interval of IASI product at 550 nm by implementing the range of conversion factor shown by [6]. However the actual factors \mathcal{F} depend on the mineralogy composition of dust and the actual size distribution with a typical range: $0.35 \leq \mathcal{F} \leq 0.55$.

MODIS dust products

MODIS Filter

If the results of 3 filters applied to MODIS deepblue aerosol product

- $\alpha < 1.4$
- $\omega_{412nm} < 0.95$
- $\tau_{412nm} - \tau_{660nm} > -0.02$

Then the MODIS optical depth τ_{550nm} values for aerosols is considered dominated by dust optical depth $\tau_{DOD-550nm}$

MODIS Filter-B

To test the sensitivity of this filter another has been created the final product is also $\tau_{DOD-550nm}$.

- $\alpha < 1.49$
- $\omega_{412nm} < 0.95$
- $\tau_{412nm} - \tau_{660nm} > -0.05$

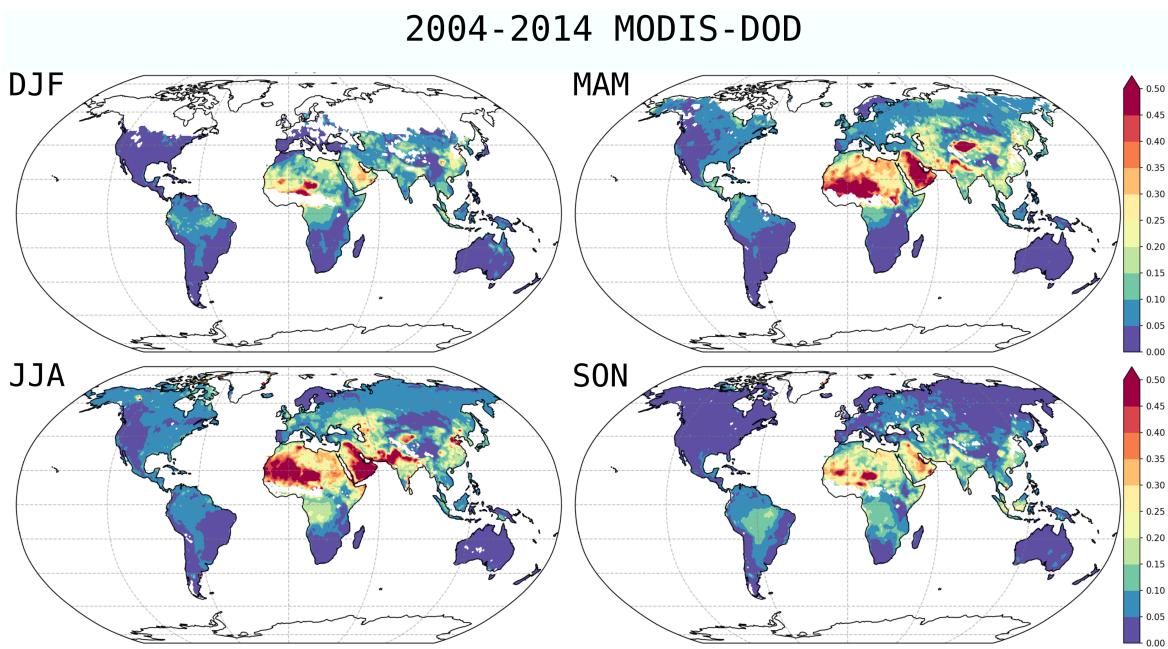

Figure S.MD.1: Climatology of MODIS-DOD product based on monthly level 3 collection 6.1. The seasonality, regional patterns and values are consistent with reference [8].

MODIS DOD

This product relies on an re-scaling of the aerosol optical depth based on a formula given by [8] together with the filter:

- $\omega_{412nm} < 0.97$
- $\tau_{DOD-550nm} = \tau_{550nm}(0.98 - 0.5089\alpha + 0.0512\alpha^2)$

The DOD is approximated as $\tau_{DOD-550nm} = \tau_{550nm}(0.98 - 0.5089\alpha + 0.0512\alpha^2)$, as this equation has been analysed for MODIS deepblue 6.1 with daily resolution [8]. We implemented over a monthly resolution and compared the seasonal properties with the Figure 1 of [8]. The global distribution and value intervals are consistent for regional and seasonal/monthly analysis with only slight differences over China and Oceania (region not included on our analysis), although maximum values are located in the same locations with close values, see Figure S.MD.1.

The Figure S.MD.2 shows comparative maps of the filters for the years 2006, 2008 and 2010, 2012. MODIS-Filter and MODIS-FilterB have similar pattern but the last is less strict filtering the dusty pixels. However, both perform well as they have signatures of dust emissions on the source regions analysed on the main paper. The MODIS-DOD instead is less strict on the source regions being potentially able to detect signatures of dust on regions not directly characterized to be dust sources. Its comparison with the last column at S.MD.2 indicates that the original τ_{550nm} is effectively decreased on most of the regions, and the S.MD.3 shows that the seasonal cycle of MODIS-Filters and MODIS-DOD is the same but the re-scaling decrease the values of MODIS-DOD consistently for all the seasons. IASI dust optical depth product shows different values as it represents the optical depth at $10\mu m$, while the seasonality is consistent for African and Middle East regions, with only remarkable differences at Taklamakan.

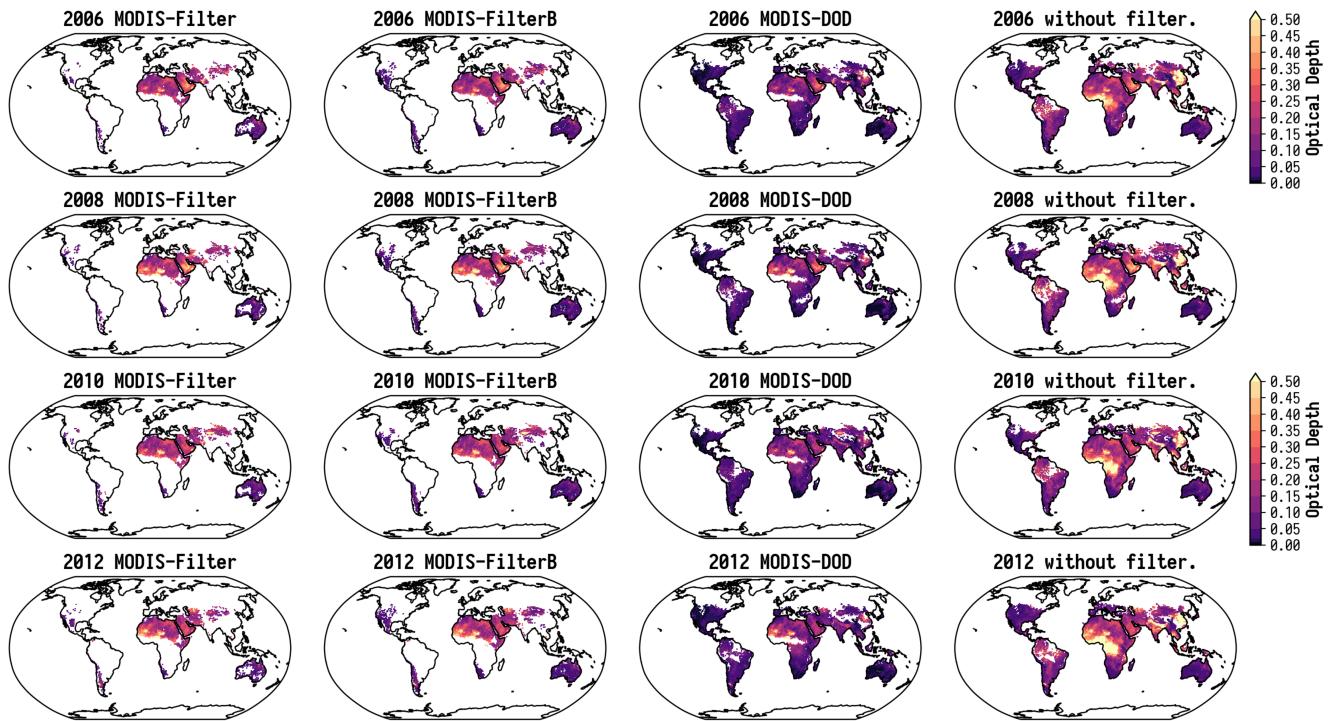

Figure S.MD.2: Comparison of the three MODIS dust related products for the same years 2006, 2008, 2010 and 2012. The last column indicate the MODIS aerosol optical depth over land without any custom filtering or scaling.

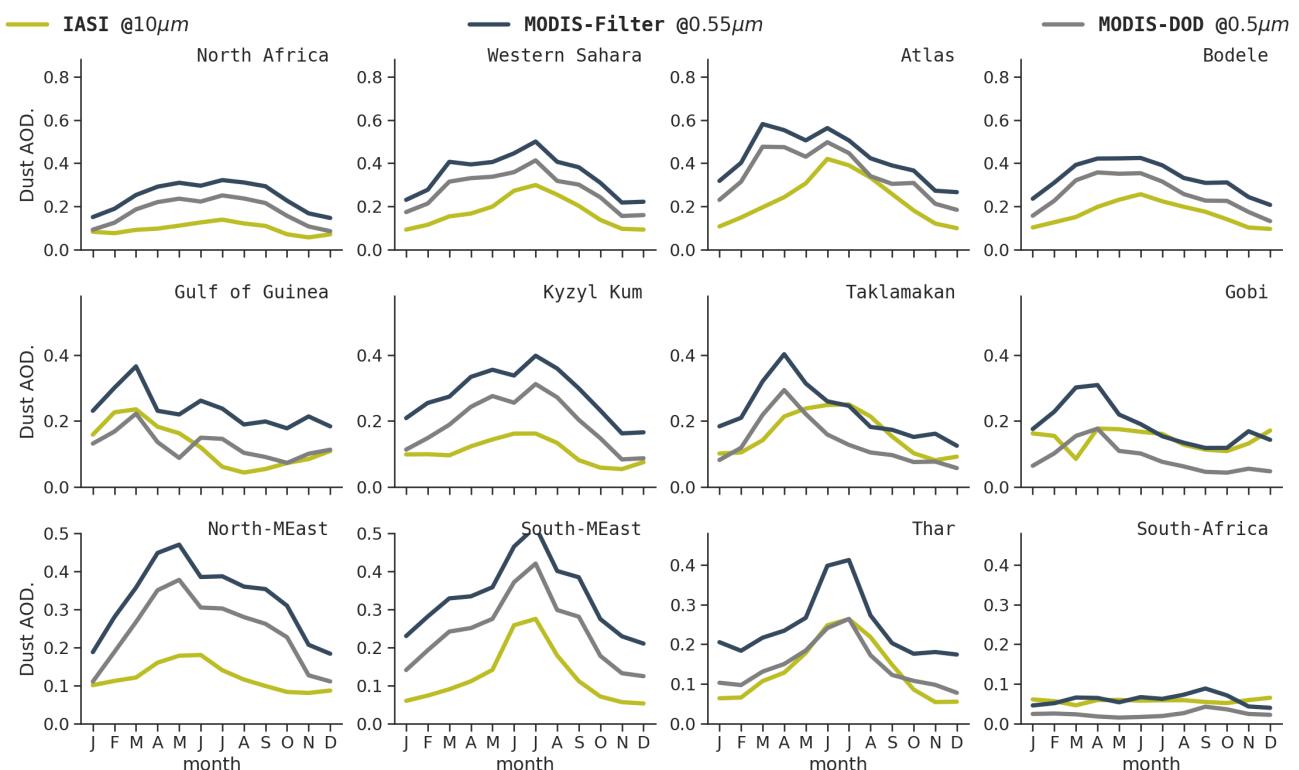

Figure S.MD.3: Comparison of seasonal optical depths of MODIS related products with IASI for regions with larger dust optical depths. The DOD retrieval from IASI is in the infrared (at $10\mu\text{m}$) therefore the values are expected to be smaller but with consistent seasonal variability [7, 6]. Period 2007-2014 due to IASI dataset availability.

6	[5.00,50.00]	-	[10.000,31.600]

Table S.MD.8: Bin intervals for CNRM-6DU, CNRM-3DU and UKESM models. The size is represented by the geometric **radius** of the dust particle in μm .

IPSL	EC-Earth	NorESM	IPSL-4DU
-	(0.5, 1.59)	(0.44,2.00)	(1.00, 1.8) $\rightarrow m_1$
(2.5, 2.00)	(2.0, 2.00)	(1.26,2.10)	(2.50, 2.0) $\rightarrow m_{2.5}$
-	-	-	(7.00, 1.9) $\rightarrow m_7$
-	-	-	(22.0, 2.0) $\rightarrow m_{22}$

Table S.MD.9: Parameters that define the shape and location of lognormal modes of dust particle size distribution. Each mode is described by two parameters: one describing an initial characteristic size at emission in μm and the other describing the width of the distribution. We report the pair of values (D_m, σ) , where D_m is the *mass median diameter* in μm . In the case of EC-Earth dust is part of a mixed mode. For the IPSL with 4 dust modes, the mode names are also given in the table as m_{D_m} . Regarding the modelling of large particles the EC-Earth dust scheme classified the particles in bins up to $8\mu\text{m}$ (with an explicit cut-off) and then the information is mapped into the two modes that define dust in the aerosol scheme. The other models doesn't have an explicit cutoff although the IPSL and NorESM are not aiming to model explicitly particles larger than $10\mu\text{m}$ and their multimodal distributions have a small probability to have those large particles. The IPSL-4DU has modelled explicitly largest particules with two modes: m_7 includes particles of about $10\mu\text{m}$, and m_{22} aim to model particles larger than $20\mu\text{m}$. Although it is not possible to assign and strict cutoff to separate both modes, IPSL-4DU is including super-coarse and giant modes.

GL: Global Dust Supplement

This supplement includes additional information for the sections 4.1 and 4.2 of main paper *Evaluation of natural aerosols in CRESCENDO-ESMs: Mineral Dust*.

Global dust cycle

This section complements the **Figure 4** of the main manuscript by showing the inter-annual variability with boxed plots, together with filtering the variables over two regions: land and Sahara & Middle-East (the filters constrain the mean fields over specific regions). The rationale of land filter analysis is to don't account regions with low values of loadings that can drive high-values of global mass extinction efficiency (MEE), whereas the Sahara & Middle-East region is focused on evaluate constraints over an area where aerosol dust emissions are dominant.

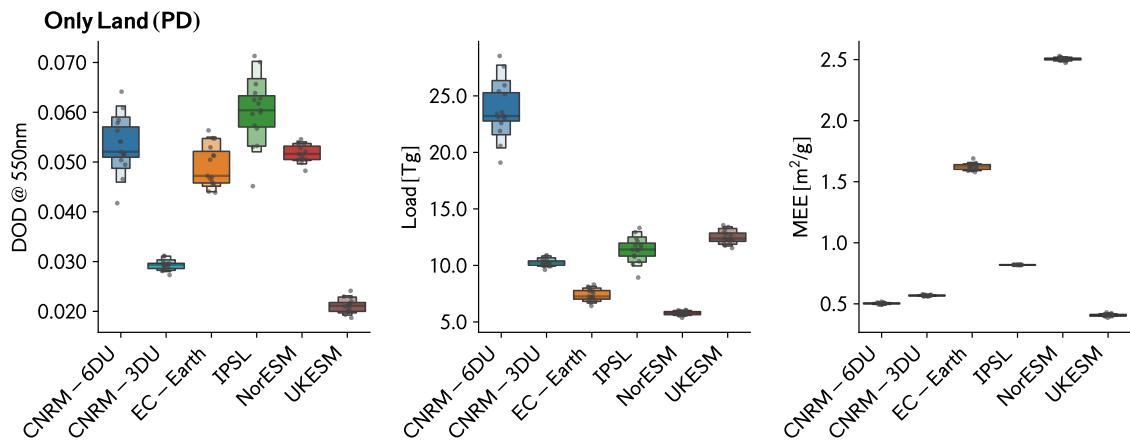

Figure S.GL.1: Constraints to dust cycle only over land. The boxen-plot represents the annual variability from 2000-2014. Scenario PD. The variability of MEE is significantly smaller than loadings and dust optical depths

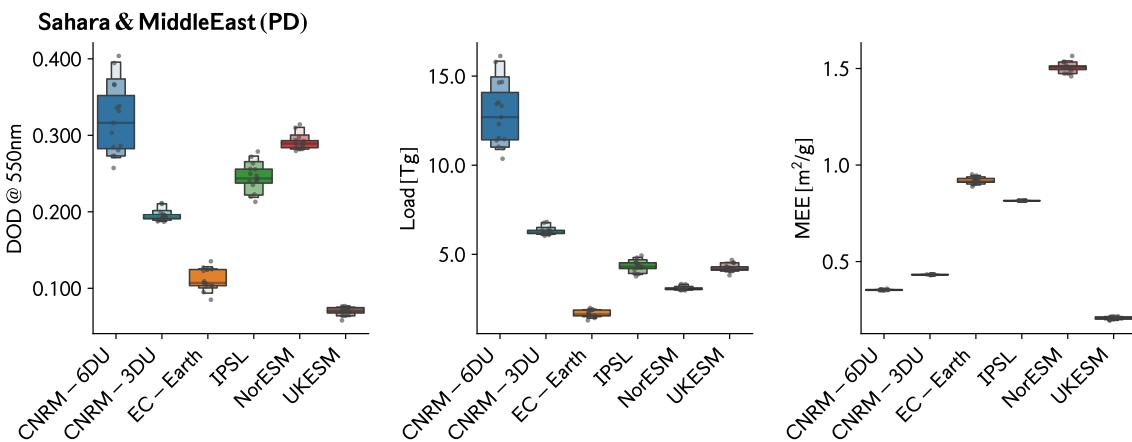

Figure S.GL.2: Constraints to dust cycle only over a Sahara & Middle-East. The boxen-plot represents the annual variability from 2000-2014. Scenario PD. The variability of MEE is significantly smaller than loadings and dust optical depths

PI experiment

These figures are the equivalents of *Figures 5 and 6* in main manuscript but for the PI scenario. The figure S.GL.3, has the three models with bin/sectional schemes. The figure S.GL.4 those models with modal description of mineral dust. The results are in agreement with PD scenario although CNRM-5DU model present large variations of mass extinction efficiency.

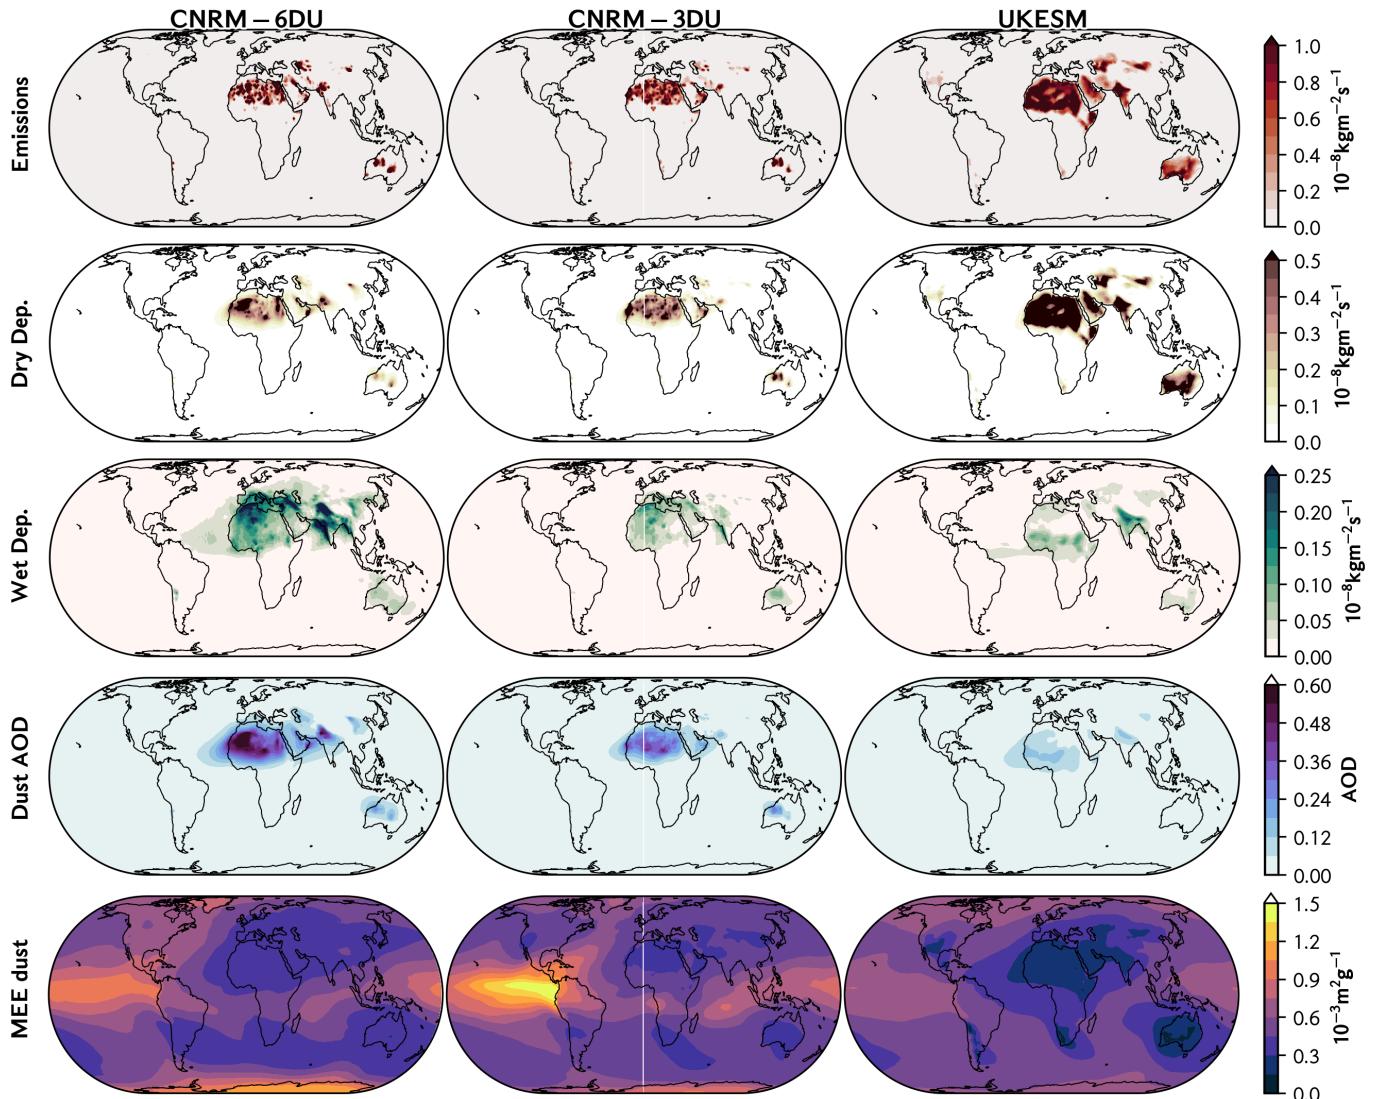

Figure S.GL.3: CRESCENDO-ESMs maps, PI scenario, describing dust properties: emission tendency, depositions tendencies, dust optical depths and mass extinction efficiency. Models CNRM-6DU, CNRM-3DU and UKESM models (bins based dust parametrization).

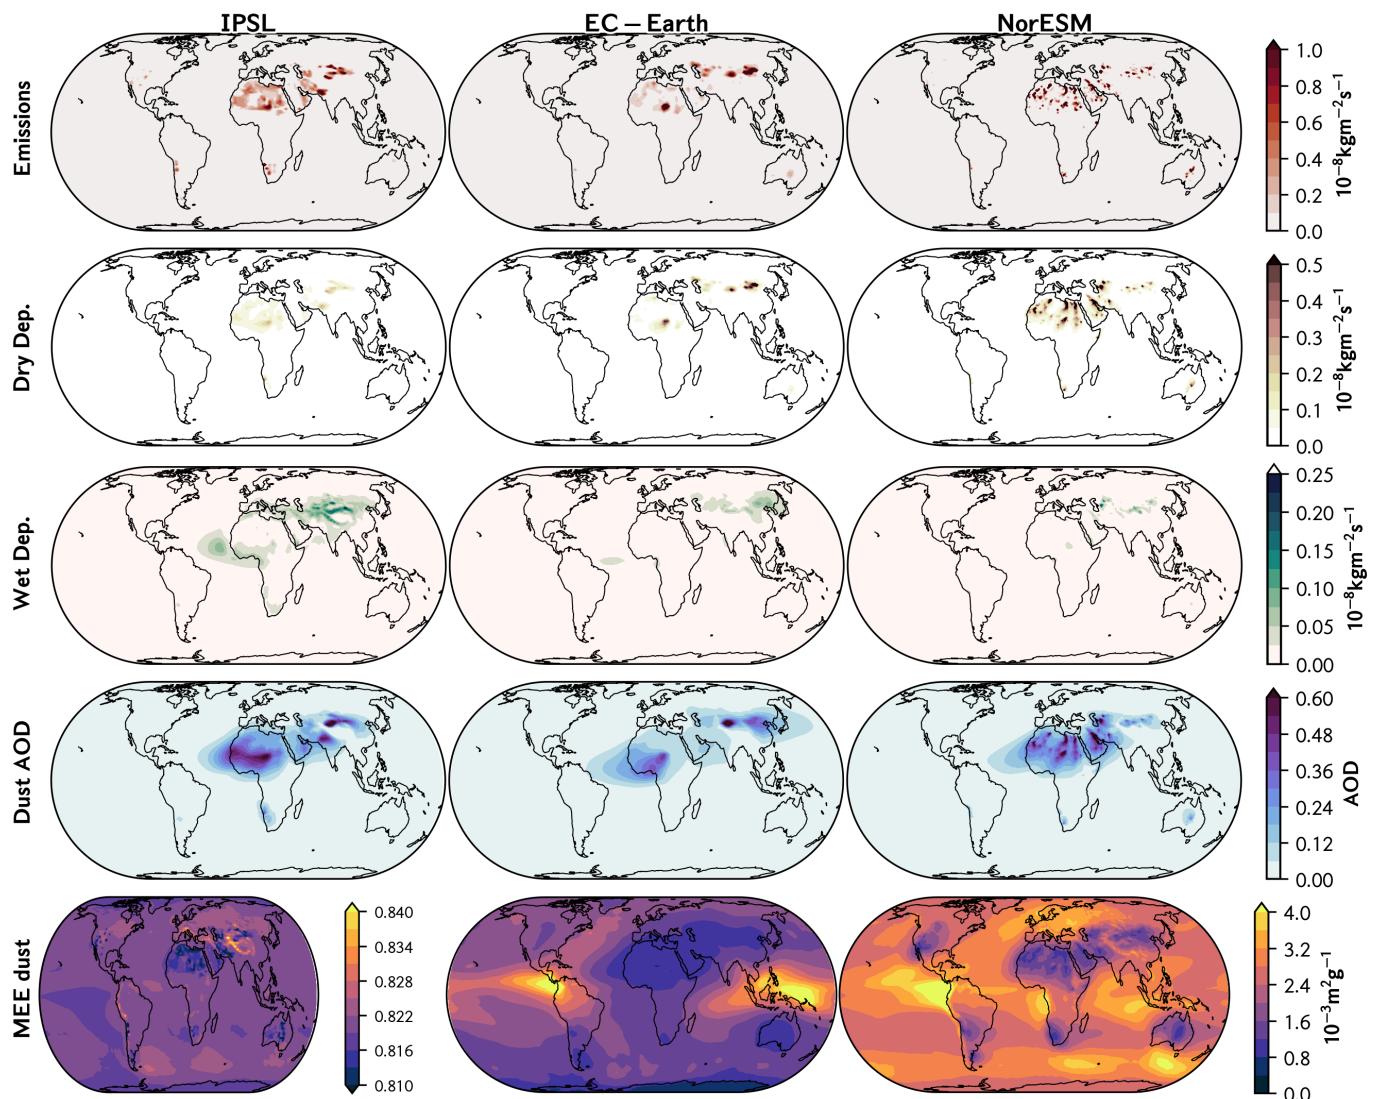

Figure S.GL.4: CRESCENDO-ESMs maps, PI scenario, describing dust properties: emission tendency, depositions tendencies, dust optical depths and mass extinction efficiency. Models IPSL, NorESM and EC-Earth models (modal based dust parametrization).

PDN experiment

These figures are the equivalents of *Figures 5 and 6* in main manuscript but for the PDN scenario. The figure S.GL.5 has the CNRM models (bin/sectional schemes). The figure S.GL.6 the IPSL and NorESM models, both with modal description of mineral dust.

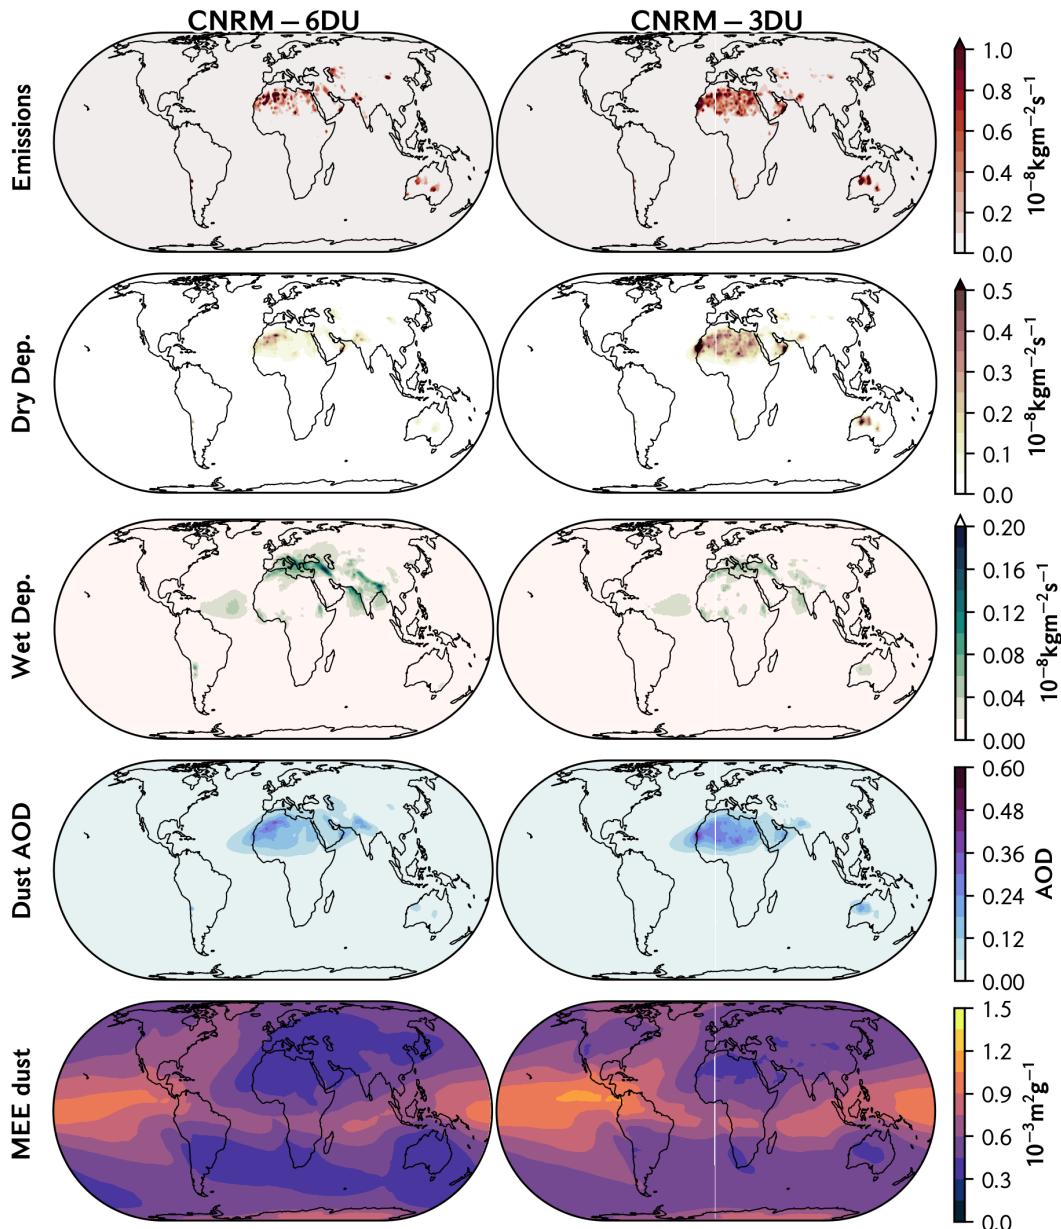

Figure S.GL.5: CRESCENDO-ESMs maps, PDN scenario, describing dust properties: emission tendency, depositions tendencies, dust optical depths and mass extinction efficiency. Models CNRM-6DU, CNRM-3DU (bins based dust parametrization).

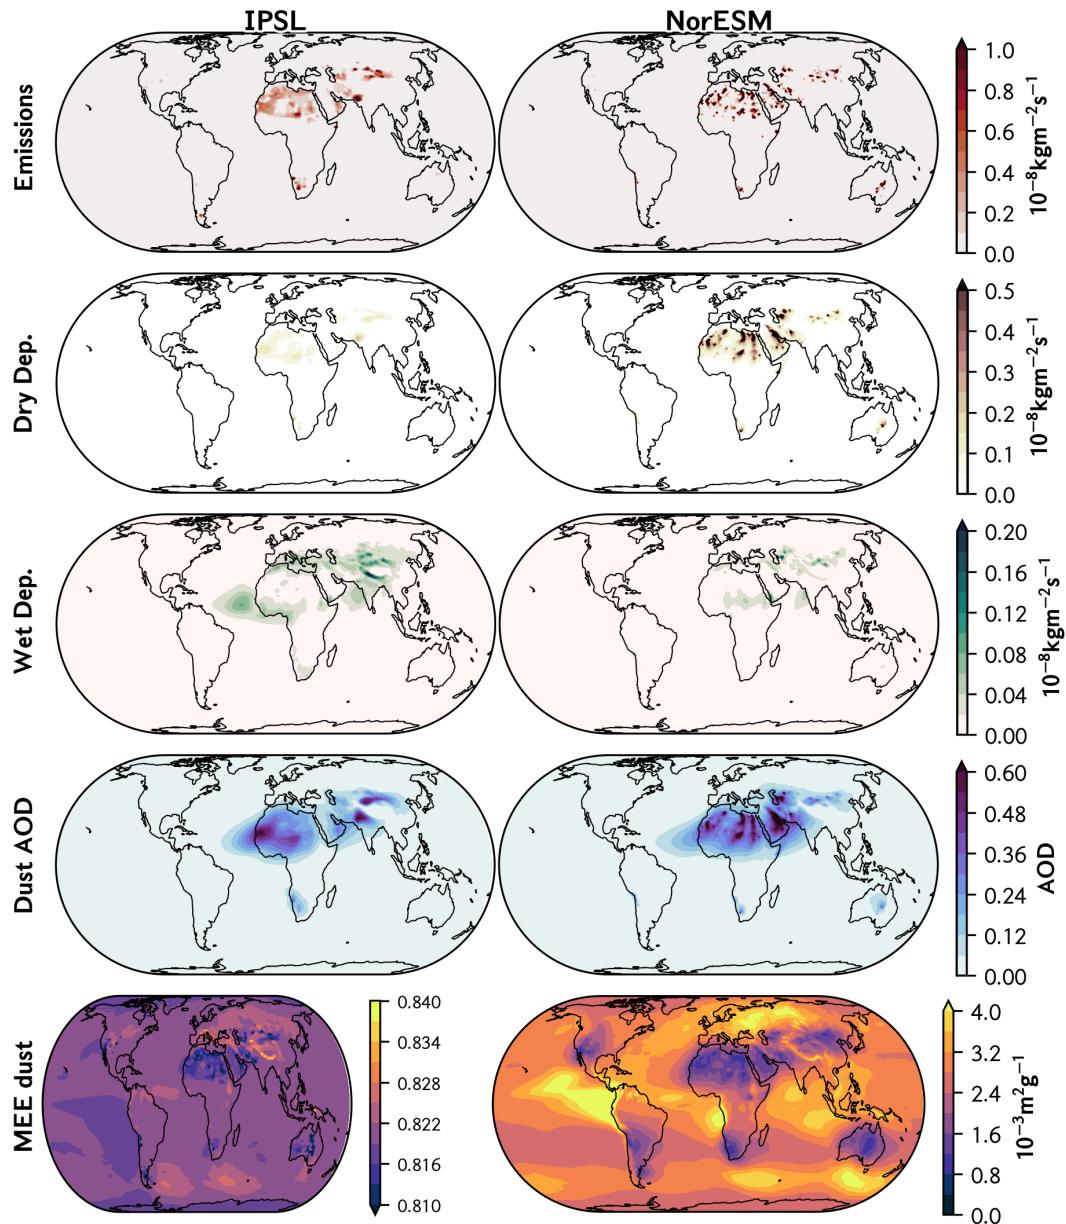

Figure S.GL.6: CRESCENDO-ESMs maps, PDN scenario, describing dust properties: emission tendency, depositions tendencies, dust optical depths and mass extinction efficiency. Models IPSL-INCA and NorESM (modal based dust parametrization).

Global Dust Budget IPSL-4DU with nudged-winds

IPSL-Mode	Emissions [Tg/yr]	Dry Dep. [Tg/yr]	Wet Dep. [Tg/yr]	Sedim. [Tg/yr]	\mathcal{R}_{dep}	Loadings [Tg]	DOD 550nm -
Mode m ₁	94.3	22.8	68.9	2.5	0.37	1.39	0.005
Mode m _{2.5}	691.3	156.9	411.4	122.4	0.68	8.21	0.012
Mode m ₇	5098.6	765.9	1282.3	3048.0	2.97	27.5	0.011
Mode m ₂₂	10316.2	370.9	231.5	9713.4	432	6.75	0.0009

Table S.GL.7: Global properties of the dust scheme with 4 modes implemented in IPSL [1] for an experiment with nudged-winds (PDN). \mathcal{R}_{dep} is the ratio of total dry deposition (with sedimentation) over wet deposition. This dust scheme includes 3 additional modes to the default IPSL scheme. Additionally it is including both number concentration and mass concentration for each mode, therefore the additional dust modes are not mixed in with other species inside a mode.

Comparison of Angstrom Exponent with MISR satellite

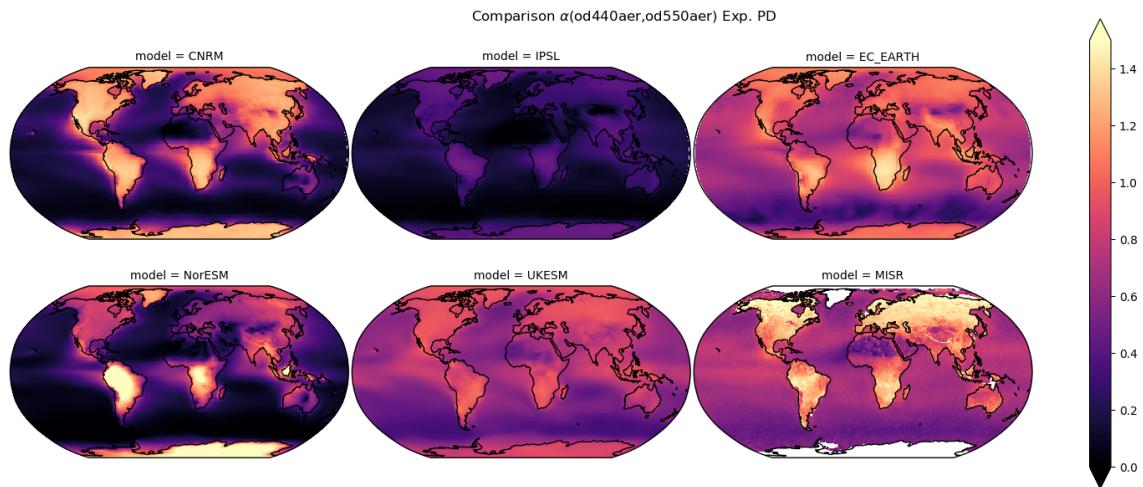

Figure S.GL.8: Comparison of Angstrom Exponent calculated from optical depths at 440nm and 550nm for CRESCENDO-ESMs and MISR satellite dataset using the same methodology. PD scenario.

DE: Dust Emissions supplement

This supplement includes additional information for the sections 4.3 main paper *Evaluation of natural aerosols in CRESCENDO-ESMs: Mineral Dust.*

Dust Emissions: additional tables

This section complements the **Table 5** of the main manuscript with the equivalent tables for PDN and PI experiments.

Table S.DE.1 Equivalent of Table 5 (global part) of main paper for PI experiment.

Table S.DE.3 Equivalent of Table 5 (global part) of main paper for PDN experiment.

Table S.DE.2 Equivalent of Table 5 (regions part) of main paper for PI experiment.

Table S.DE.4 Equivalent of Table 5 (regions part) of main paper for PDN experiment.

Dust Emissions: normalized maps

This section complements the **Figure 7** of the main manuscript with the equivalent tables for PDN and PI experiments.

Fig. S.DE.5 Equivalent of Figure 7 of main paper for PI experiment.

Dust Emissions: additional tables

Table S.DE.1: Emissions [$Tg\ yr^{-1}$] for Pre-Industrial (PI) experiment. Globally and over Land/Coastlines. (*) Denotes those models with bin sizes larger than $10\mu m$. Sahara desert emissions and its percentage over total emissions is obtained from the sum of the regions: Western Sahara, Mali, Bodele and North Sahara, so it is not including Sahel.

Dust Emissions: normalized maps

As commented on the main text a direct comparison of the normalized emission maps with observations need to translate the observed frequency of dust events into a dust emission flux rate [1]. However still it is possible to compare the qualitative location of hot-spots over different regions.

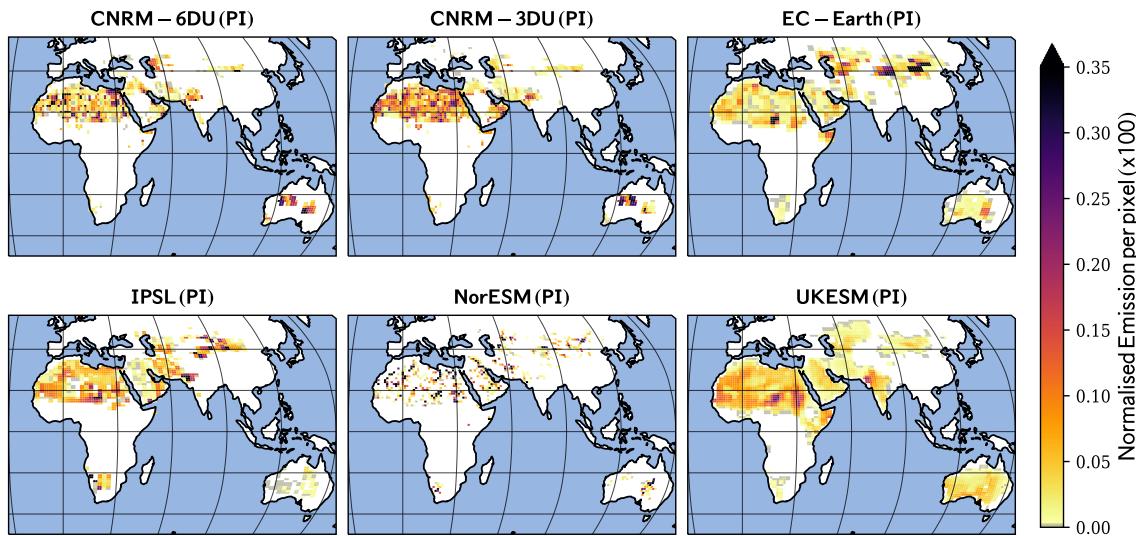

Figure S.DE.5: Normalised map of emissions (x100) over NorESM grid resolution. Experiment with pre-industrial aerosol and chemistry forcings (PI). We used a conservative near-neighbour interpolation to create emission maps that preserve global values on higher resolutions, then the maps were normalised to have a common comparison scale. The color-bar represents the normalised emission tendencies per grid with range [0,100]

DOD: Dust Optical Depth supplement

This supplement includes additional information for the sections 4.5 main paper *Evaluation of natural aerosols in CRESCENDO-ESMs: Mineral Dust.*

Dust Optical Depth: seasonal cycle

This section complements the **Figure 10** of the main manuscript by showing the regional dust seasonal cycle for experiments different from PD, and with not normalized values.

Fig. S.DOD.1 Analogous of Figure 10 of main paper for PDN experiment.

Fig. S.DOD.2 Analogous of Figure 10 of main paper for PI experiment.

Fig. S.DOD.3 Similar to Figure 10 of main paper but without normalizing the seasonal cycle (PD experiment).

Fig. S.DOD.4 Similar to Figure 10 of main paper but without normalizing the seasonal cycle (PDN experiment).

Fig. S.DOD.5 Similar to Figure 10 of main paper but without normalizing the seasonal cycle (PI experiment).

Fig. S.DOD.6 Comparison of model-ensemble anomalies of seasonal cycle between PD and PI experiments.

Dust Optical Depth: skill dust optical depth

This section complements the **Figure 11** of the main manuscript by showing the skill with another correlation statistics (the Spearman rank correlation) for MODIS-DOD. By assuming that the time-series that the monthly time-series between models (dust optical depth at $0.55 \mu m$) and IASI (dust optical depth product at $10 \mu m$) will have similar seasonal cycle the skill of the models is ascertained against the IASI dust product (see **Figure Supp.MD.3**).

Fig. S.DOD.7 Equivalent of Figure 10 of main paper but for Spearman Correlation.

Fig. S.DOD.8 Equivalent of Figure 10 of main paper with correlations against IASI dust product (and Pearson correlation).

Fig. S.DOD.9 Equivalent of Figure 10 of main paper with correlations against IASI dust product (and Spearman correlation).

Seasonal Cycle of Aeronet Dusty Stations

Fig. S.DOD.10 Seasonal Cycle Optical Depths over Sahel Region. Models CNRM, CNRM-3DU, IPSL (PD experiment)

Fig. S.DOD.11 Seasonal Cycle Optical Depths over Sahel Region. Models NorESM and EC-Earth (PD experiment)

Dust Optical Depth: seasonal cycle

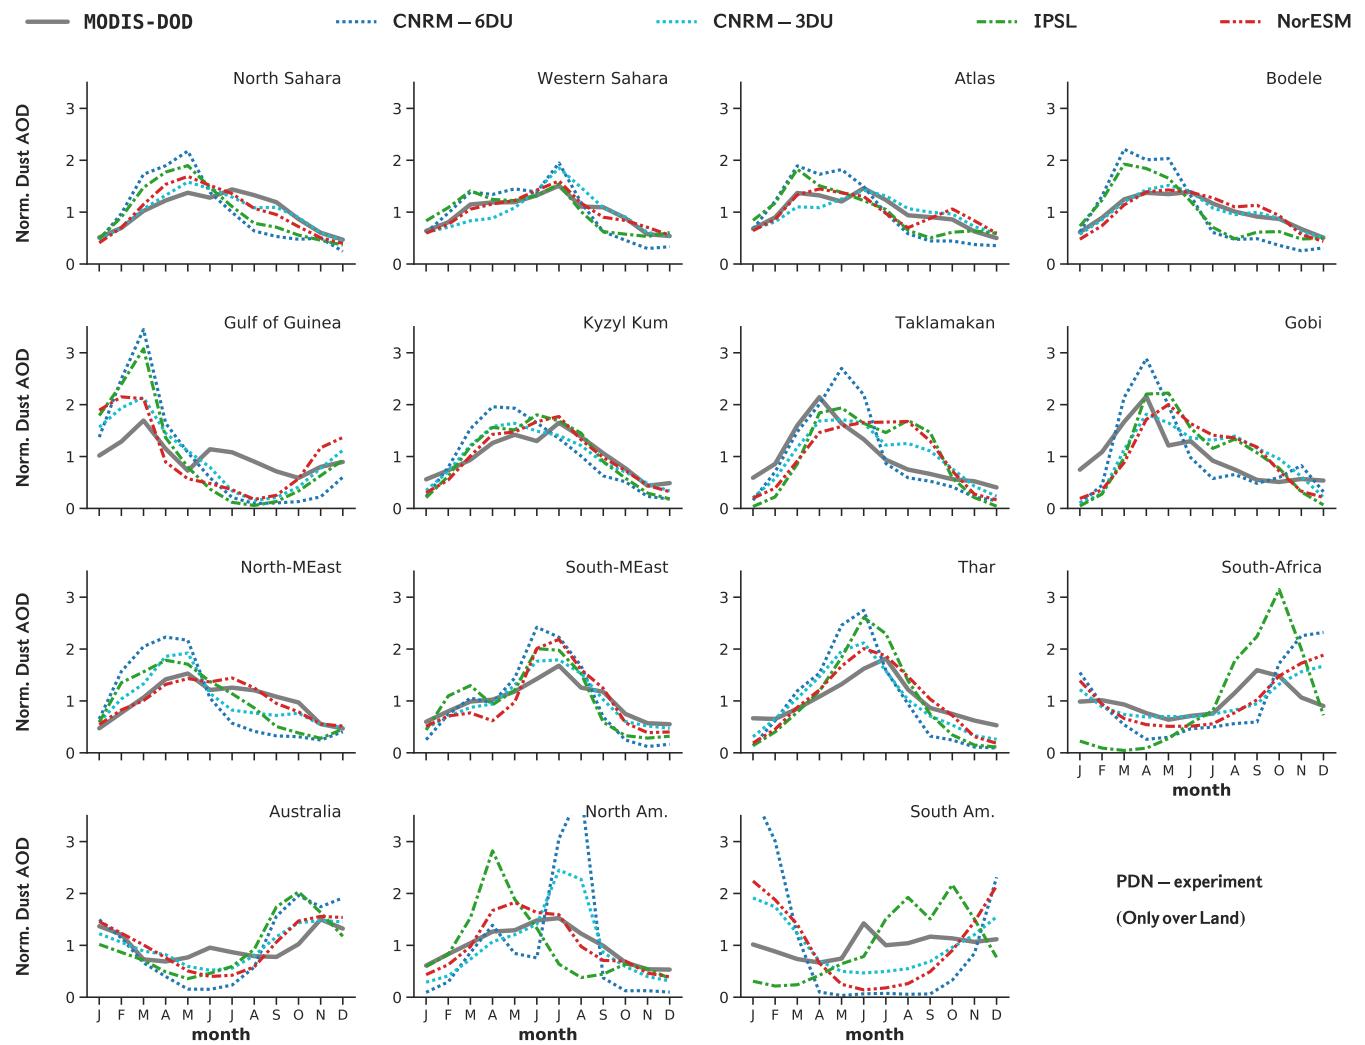

Figure S.DOD.1: The seasonal cycle of Dust Optical Depth relative to annual mean value as modelled by each CRESCENDO-ESM over 15 regions and for the PDN experiment. Compared against the DAOD product described on the supplementary information (MD) which is a derived dust optical depth over land based on MODIS deep-blue retrievals [1].

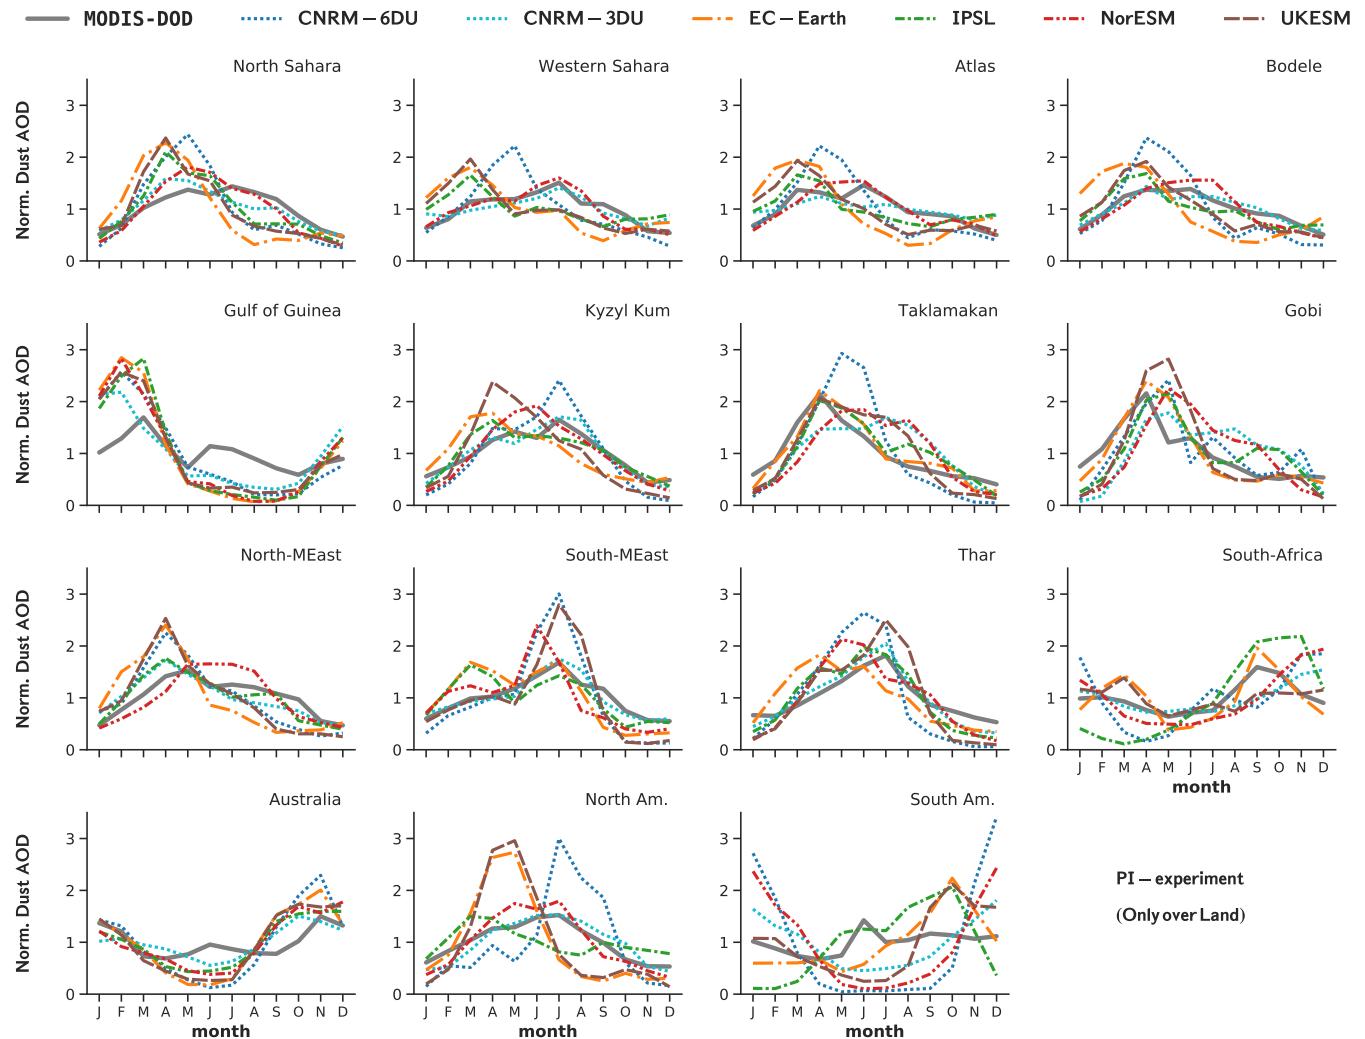

Figure S.DOD.2: The seasonal cycle of Dust Optical Depth relative to annual mean value as modelled by each CRESCENDO-ESM over 15 regions and for the PI experiment. Compared against the DAOD product described on the supplementary information (MD) which is a derived dust optical depth over land based on MODIS deep-blue retrievals [1].

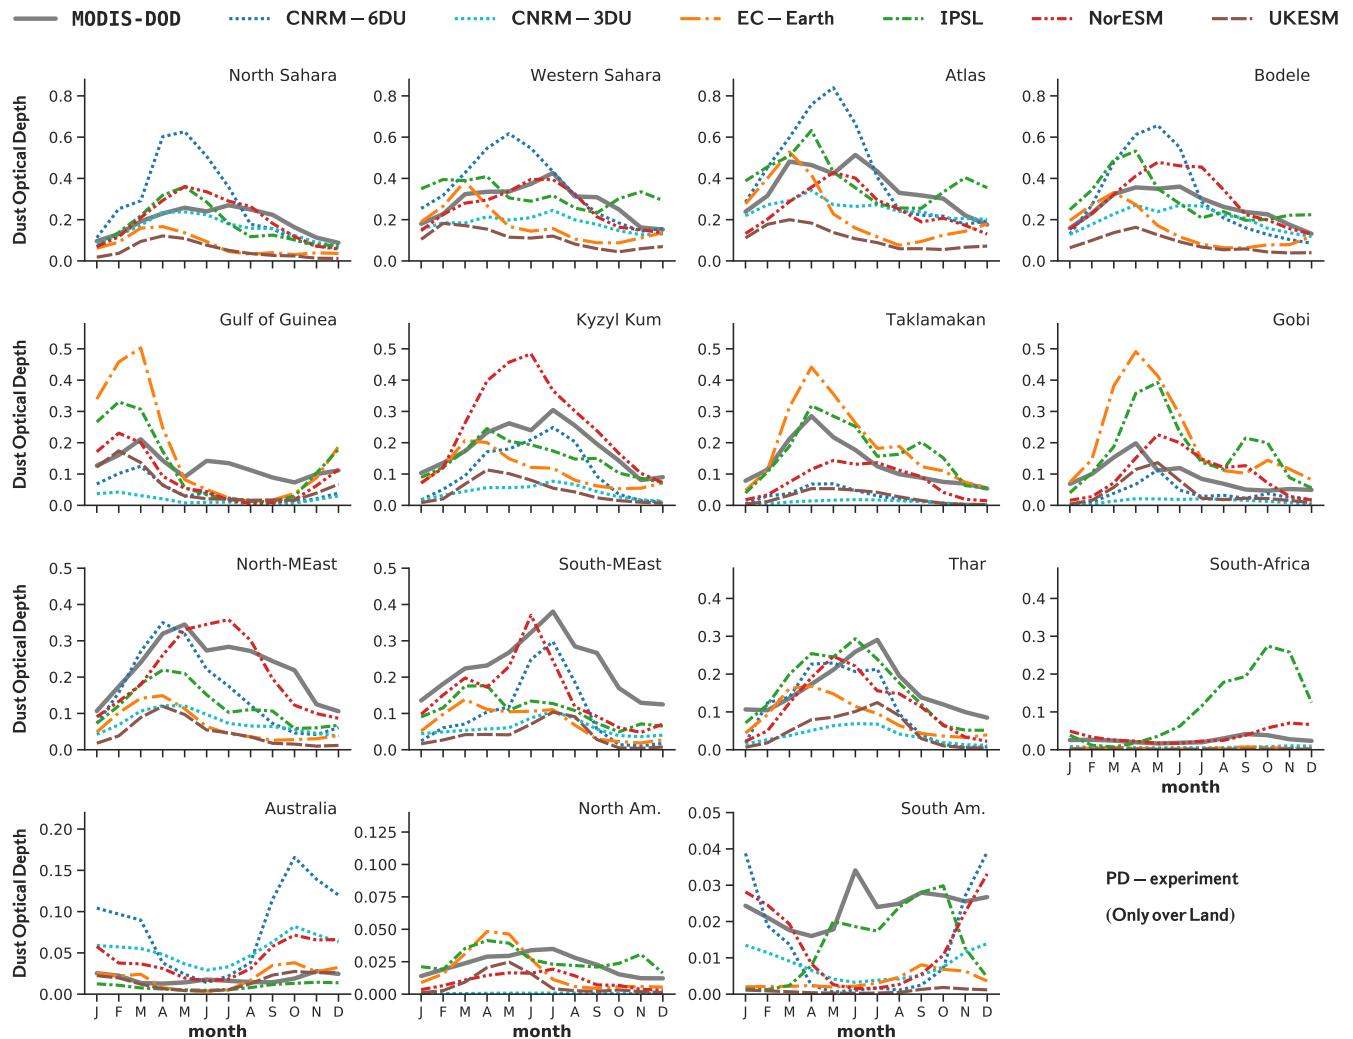

Figure S.DOD.3: The seasonal cycle of Dust Optical Depth as modelled by each CRESCENDO-ESM over 15 regions and for the PD experiment. Compared against DAOD product described on the supplementary information (MD) which is a derived dust optical depth over land based on MODIS deep-blue retrievals [1].

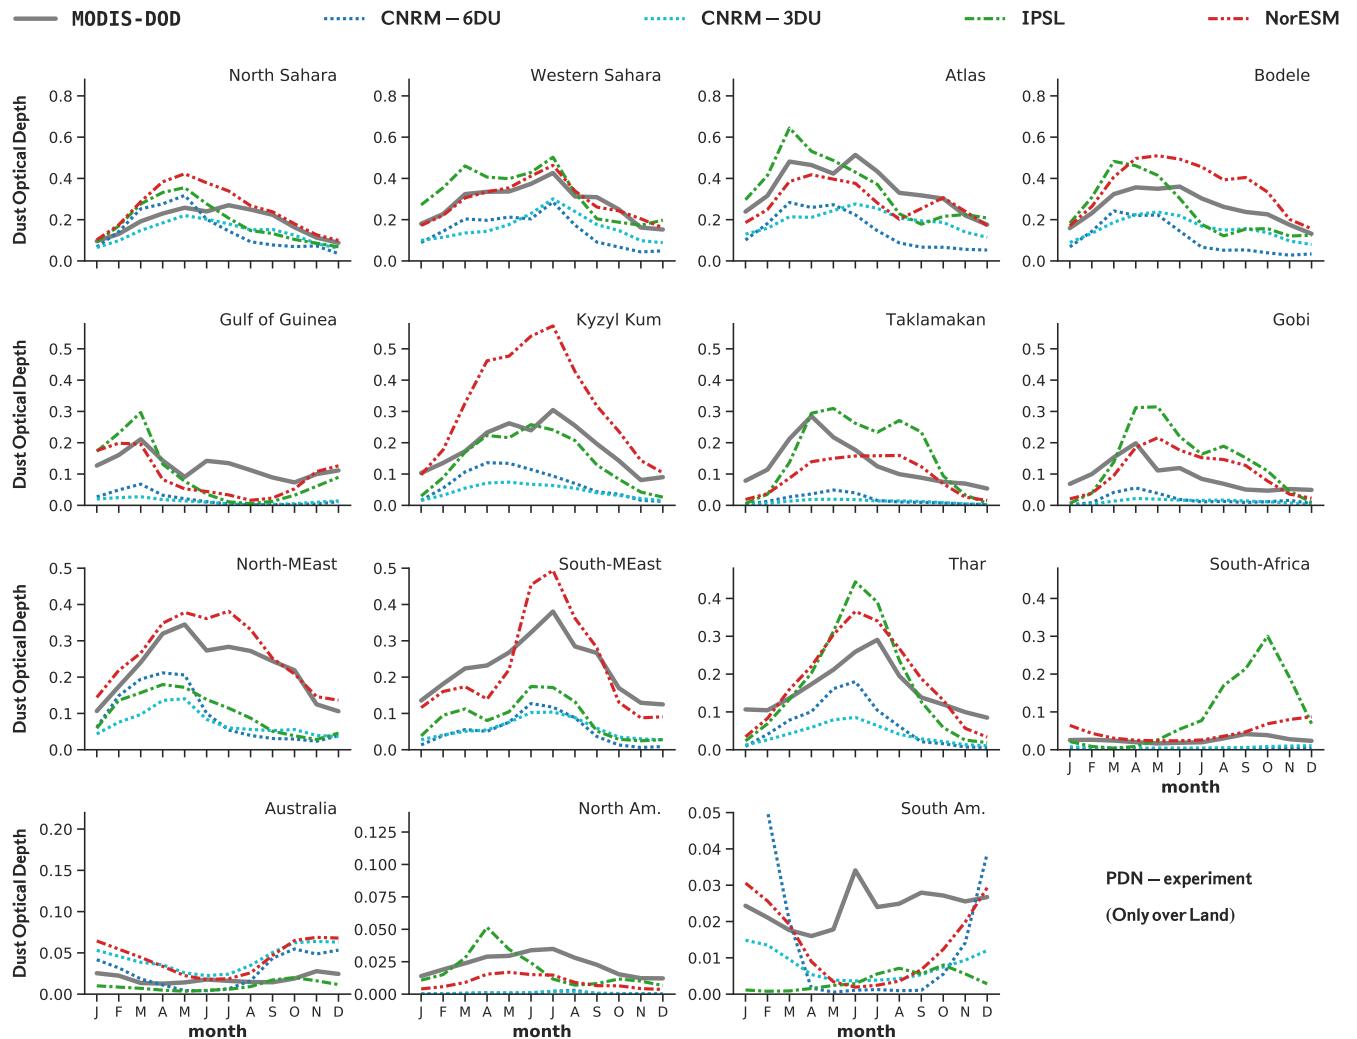

Figure S.DOD.4: The seasonal cycle of Dust Optical Depths modelled by each CRESCENDO-ESM over 15 regions and for the PDN experiment. Compared against DAOD product described on the supplementary information (MD) which is a derived dust optical depth over land based on MODIS deep-blue retrievals [1].

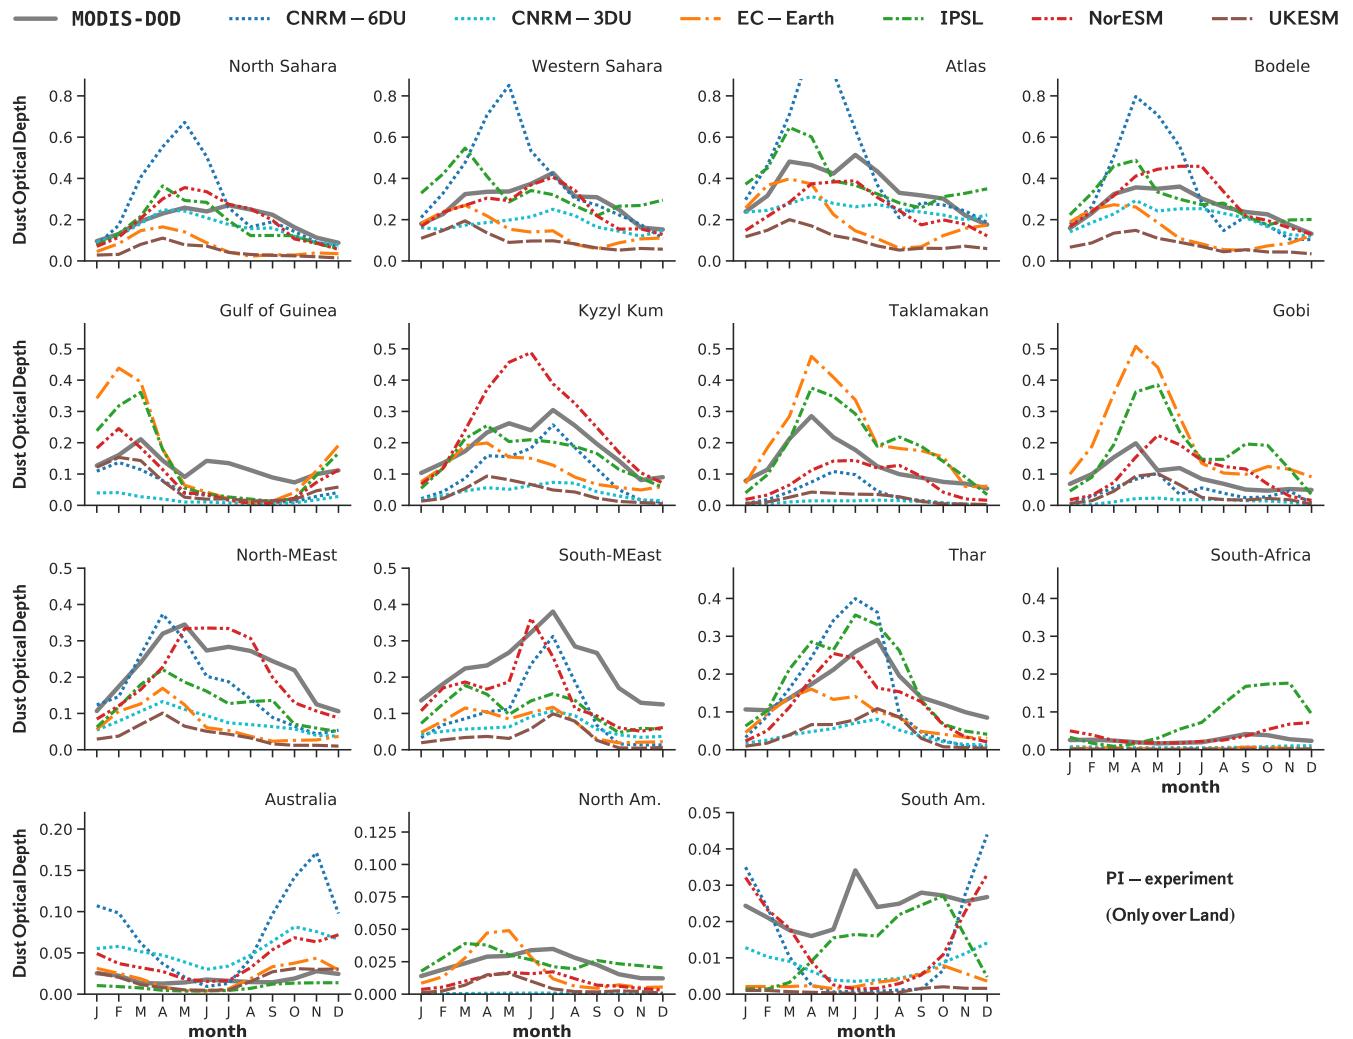

Figure S.DOD.5: The seasonal cycle of Dust Optical Depth as modelled by each CRESCENDO-ESM over 15 regions and for the PI experiment. Compared against DOD product described on the supplementary information (MD) which is a derived dust optical depth over land based on MODIS deep-blue retrievals [1].

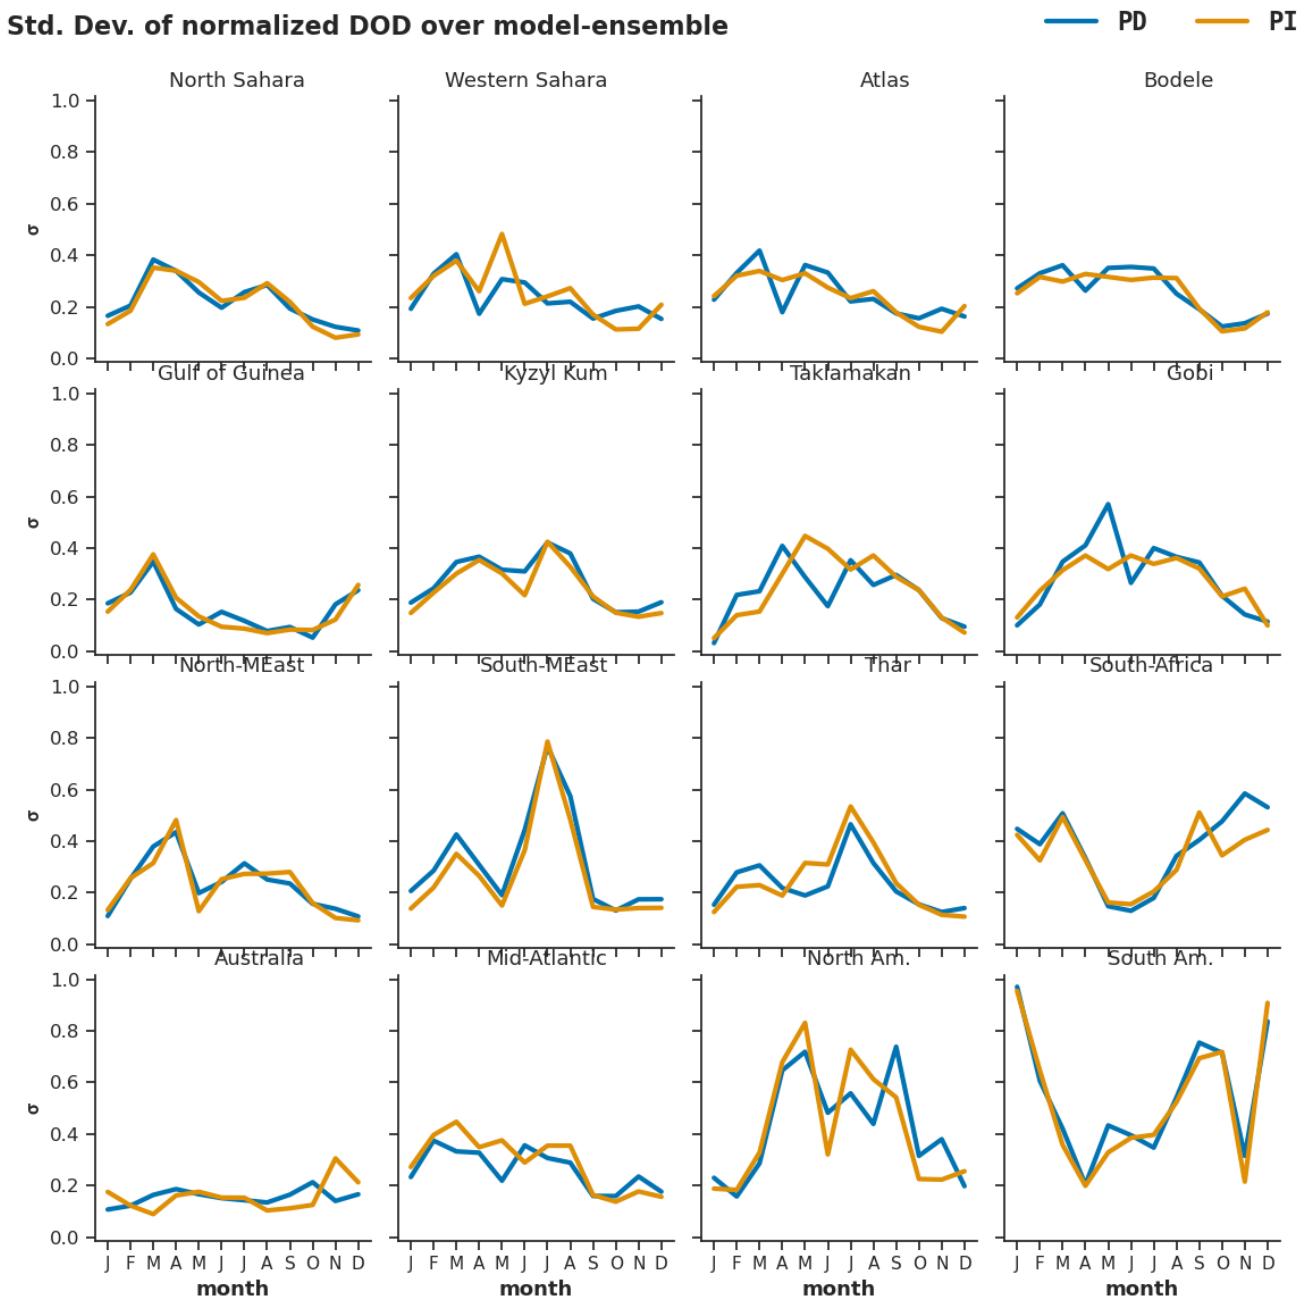

Figure S.DOD.6: Analysis of the standard deviation within the multi-model ensemble of normalized dust optical depth seasonal values. The figure compares the variability in the model-ensemble between PD and PI experiments.

Dust Optical Depth: skill dust optical depth

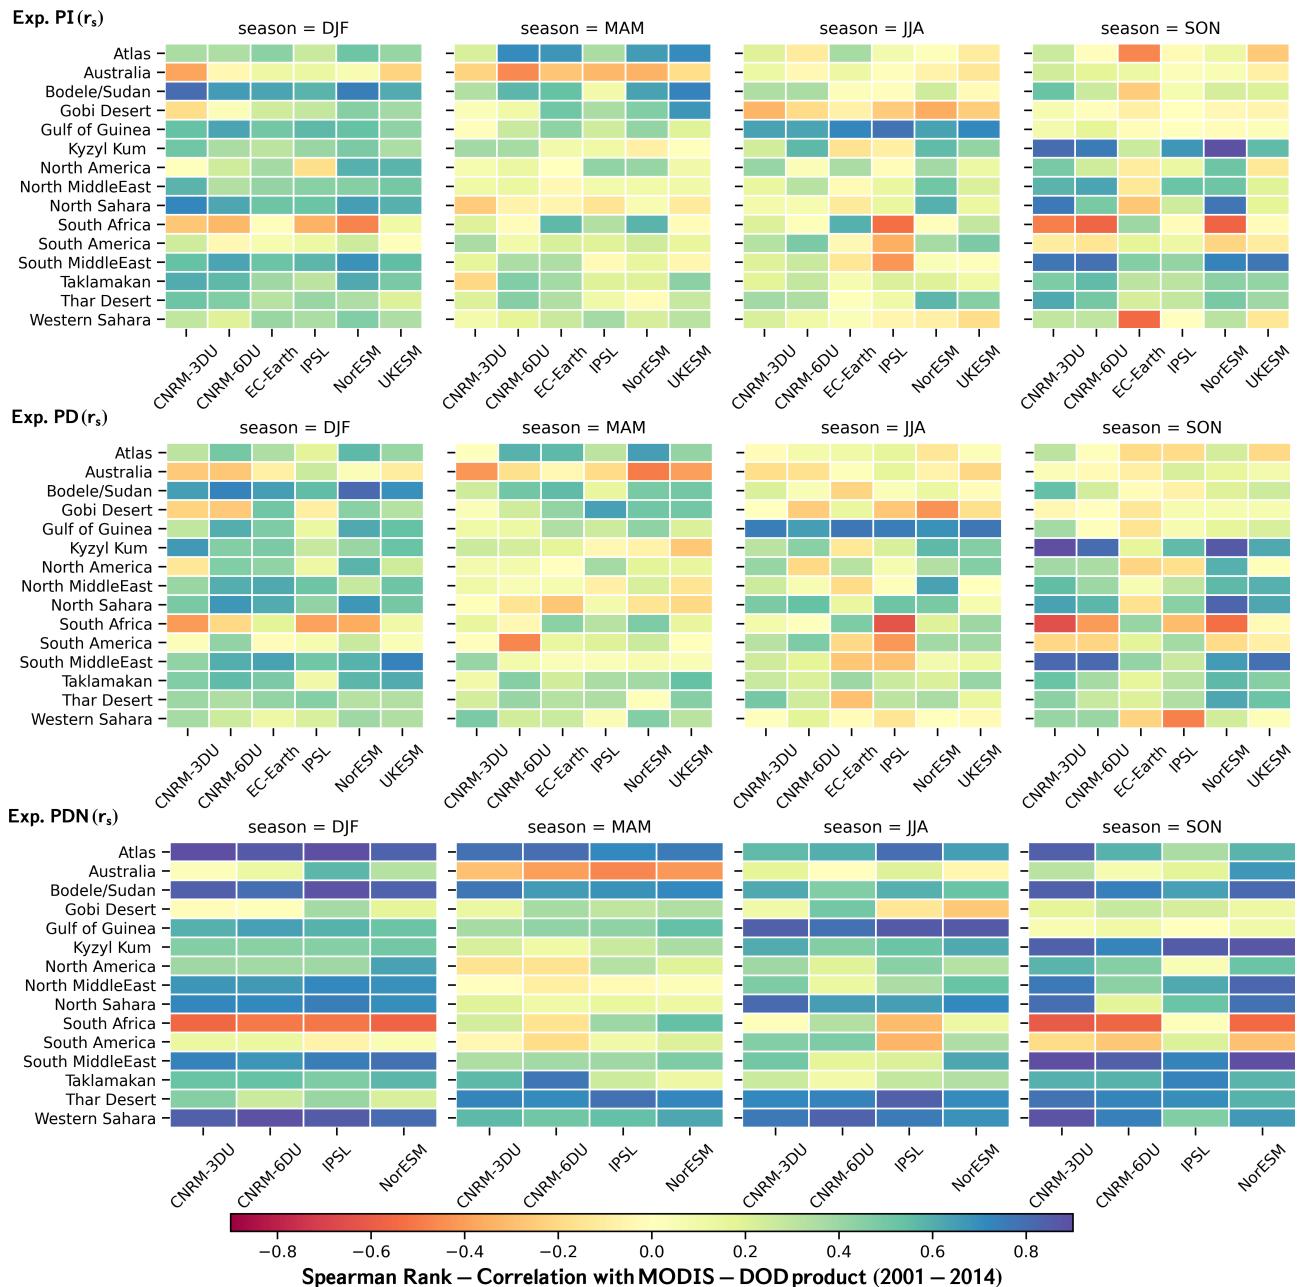

Figure S.DOD.7: Skill of CRESCENDO-ESMs for the DAOD over 15 regions and defined by the Spearman correlation between ESM time-series of dust optical depths for each season and region and that from MODIS-DOD. Time interval 2001-2014.

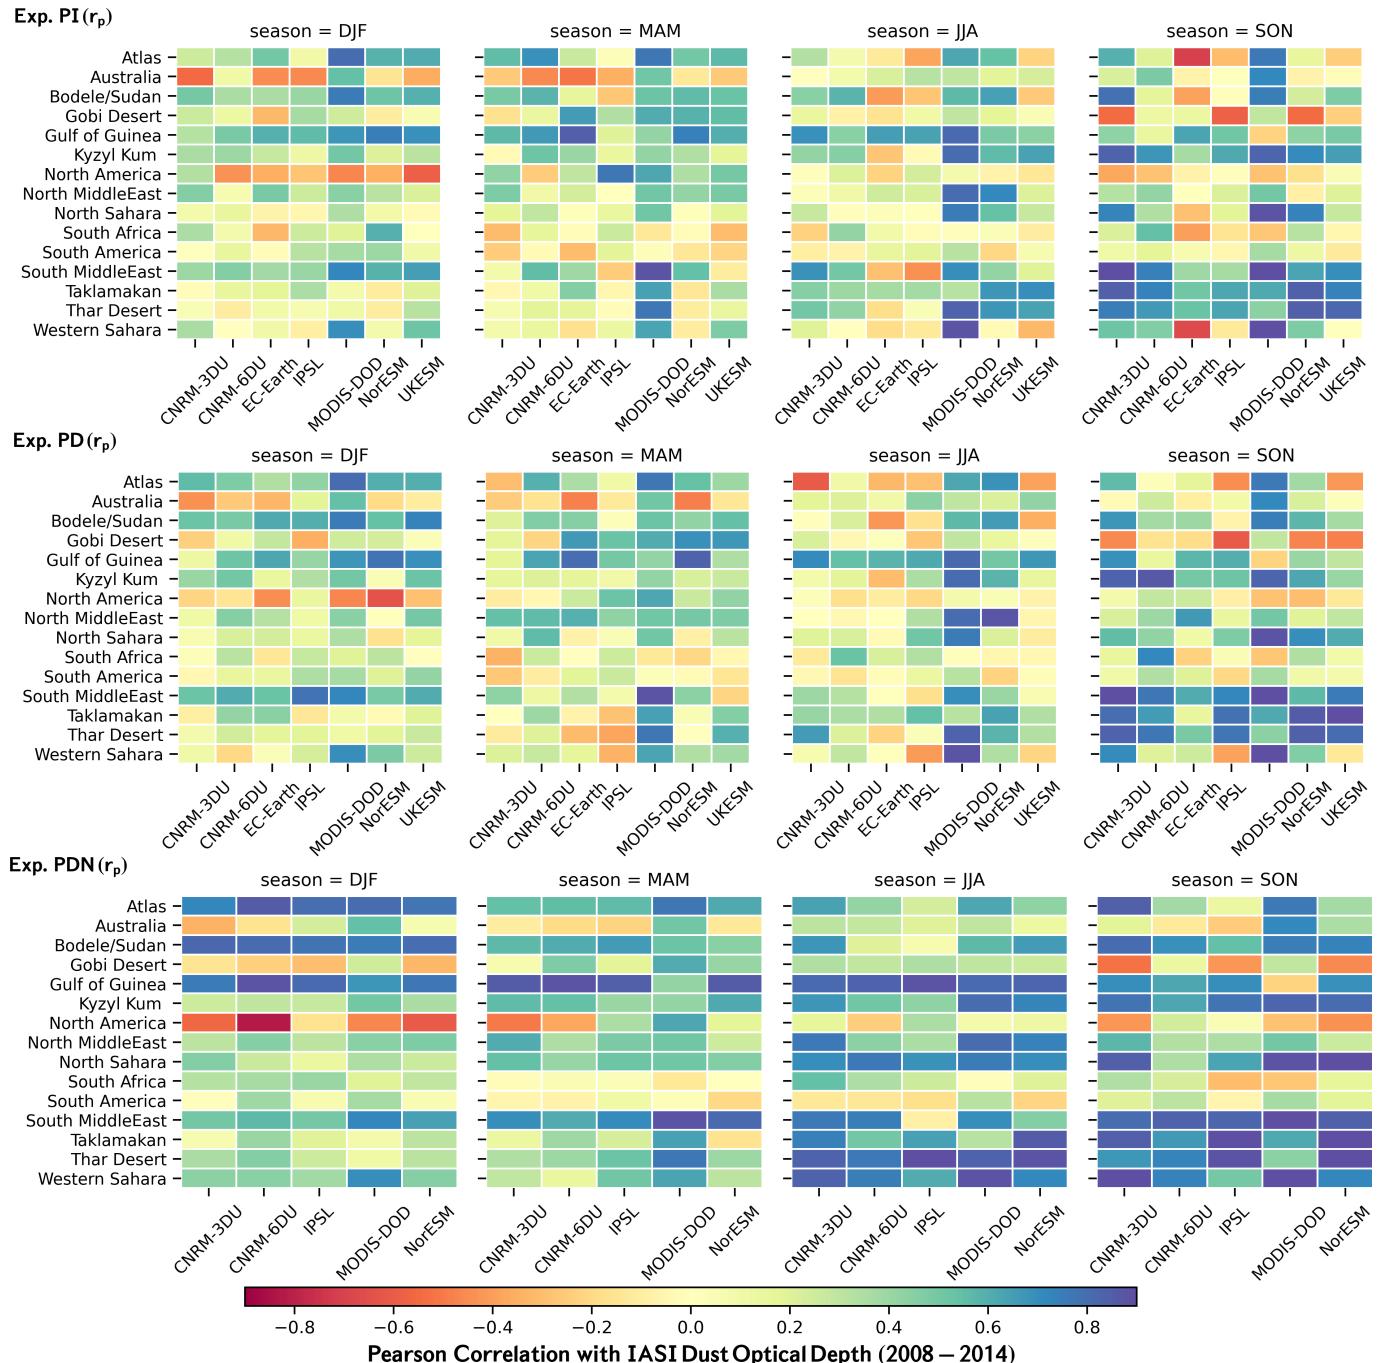

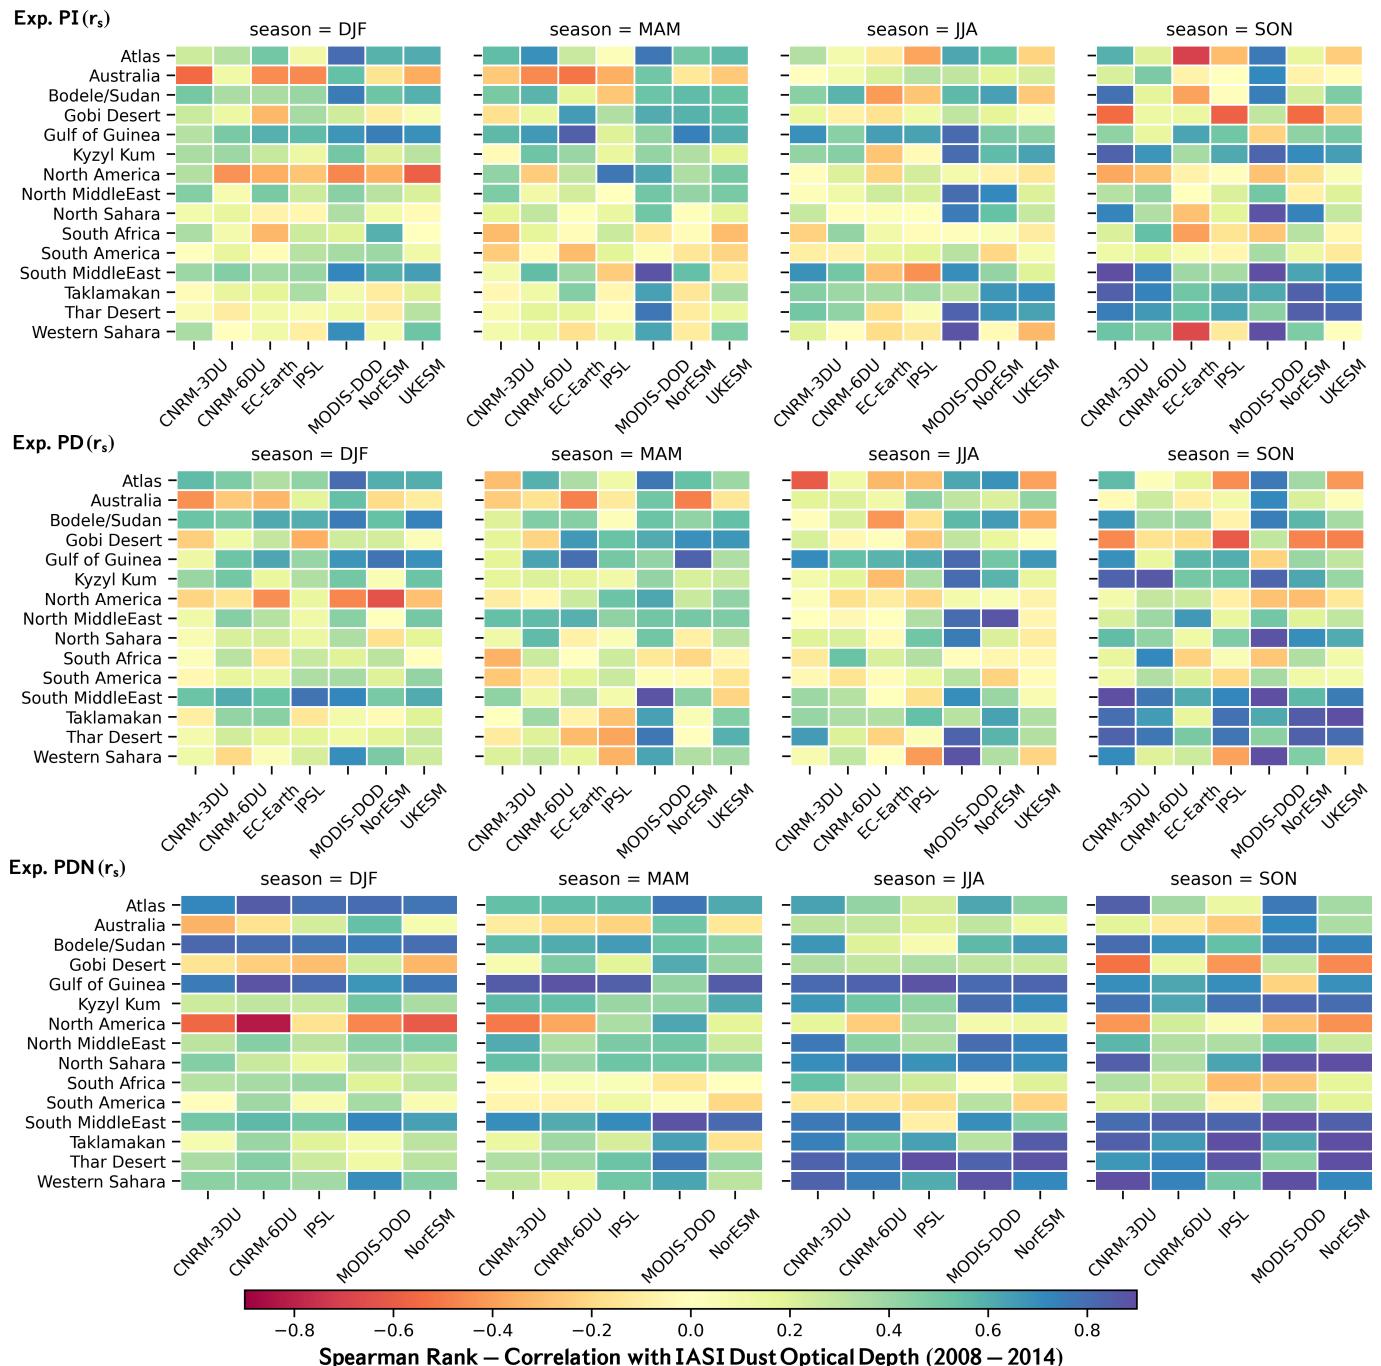

Figure S.DOD.8: Skill of CRESCENDO-ESMs for the DAOD over 15 regions and defined by the Pearson correlation between ESM time-series of dust optical depths for each season and region and that from IASI. Time interval 2008–2014.

Seasonal Cycle of AERONETv3 Stations

Figure S.DOD.10: Comparison of ESM models CNRM-6DU, CNRM-3DU and IPSL (PD simulation) against AERONETv3 stations over Sahel region.

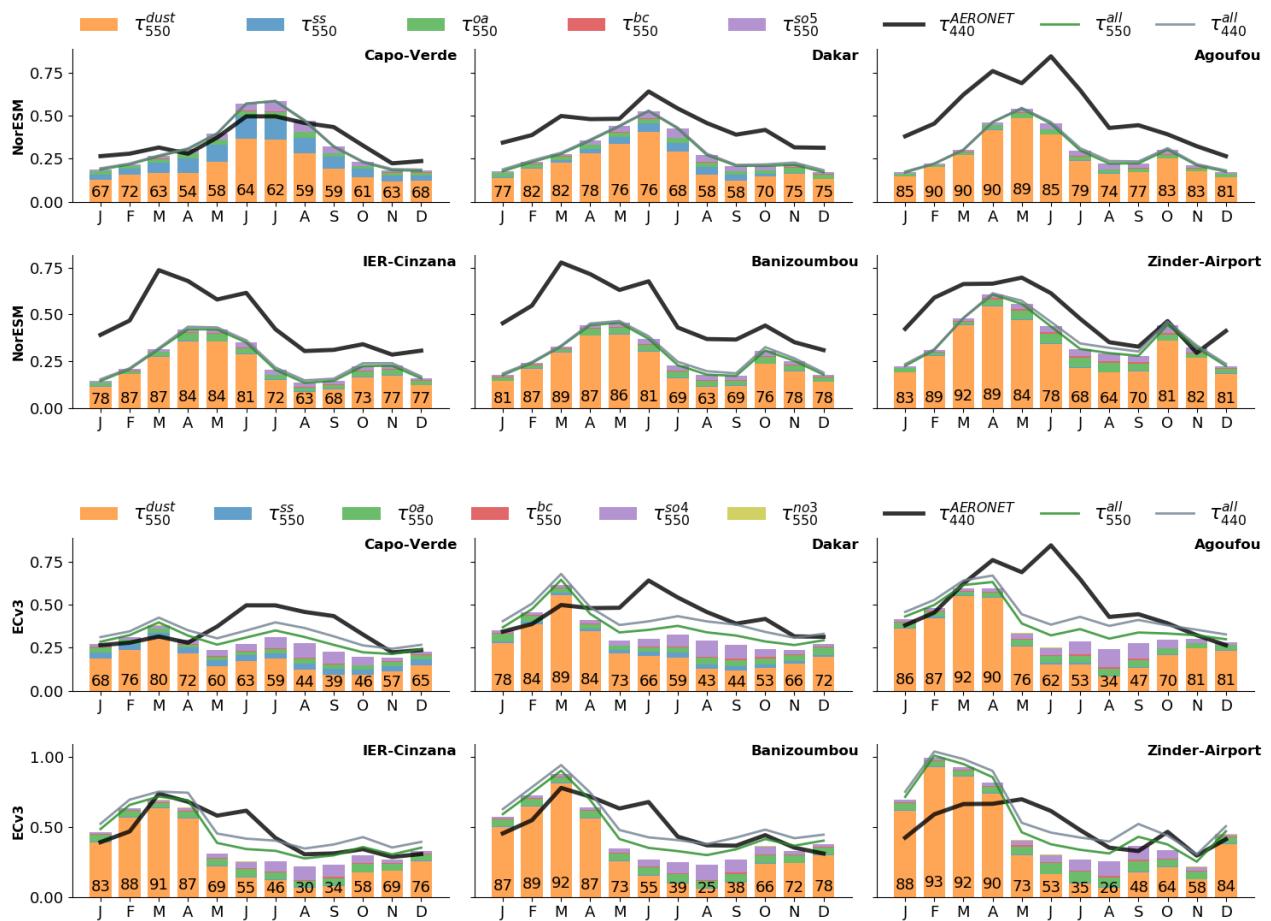

Figure S.DOD.11: Comparison of ESM models NorESM and EC-Earth (PD simulation) against AERONETv3 stations over Sahel region.
