

Supplement of

Exploring the elevated water vapor signal associated with the free tropospheric biomass burning plume over the southeast Atlantic Ocean

Kristina Pistone et al.

ERA5 versus ERA-Interim

In comparing the ERA5 reanalysis with ERA-Interim, a few features stand out. First, we note that for many parameters, the general spatial patterns over the southeast Atlantic are consistent between the two products. Figure S1 shows generally similar spatial patterns, yet upon closer examination the differences at a given point in time are large (Figure S1). This results in generally better agreement between ERA5 and the observations, as compared with ERA-Interim (Figure S2).

For water vapor specifically, ERA-Interim still generally captures the presence of an elevated water vapor signal in the altitudes above the boundary layer, but often this high-humidity air was displaced to a lower altitude than what was observed (e.g., Figure S2).

10 It is not clear which changes from ERA-Interim to ERA5 may be responsible for this improvement, and previous work has shown the differences between the two are not due to any one factor, i.e. not solely due to ERA5's improved spatiotemporal resolution (Hoffmann et al., 2019). Nonetheless, it is reassuring that this newest ECMWF product agrees so well with the aircraft observations, and this gives us confidence that the ERA5 meteorology may be consistent with real-world meteorology over the continental source region as well.

15 Supplementary Figures

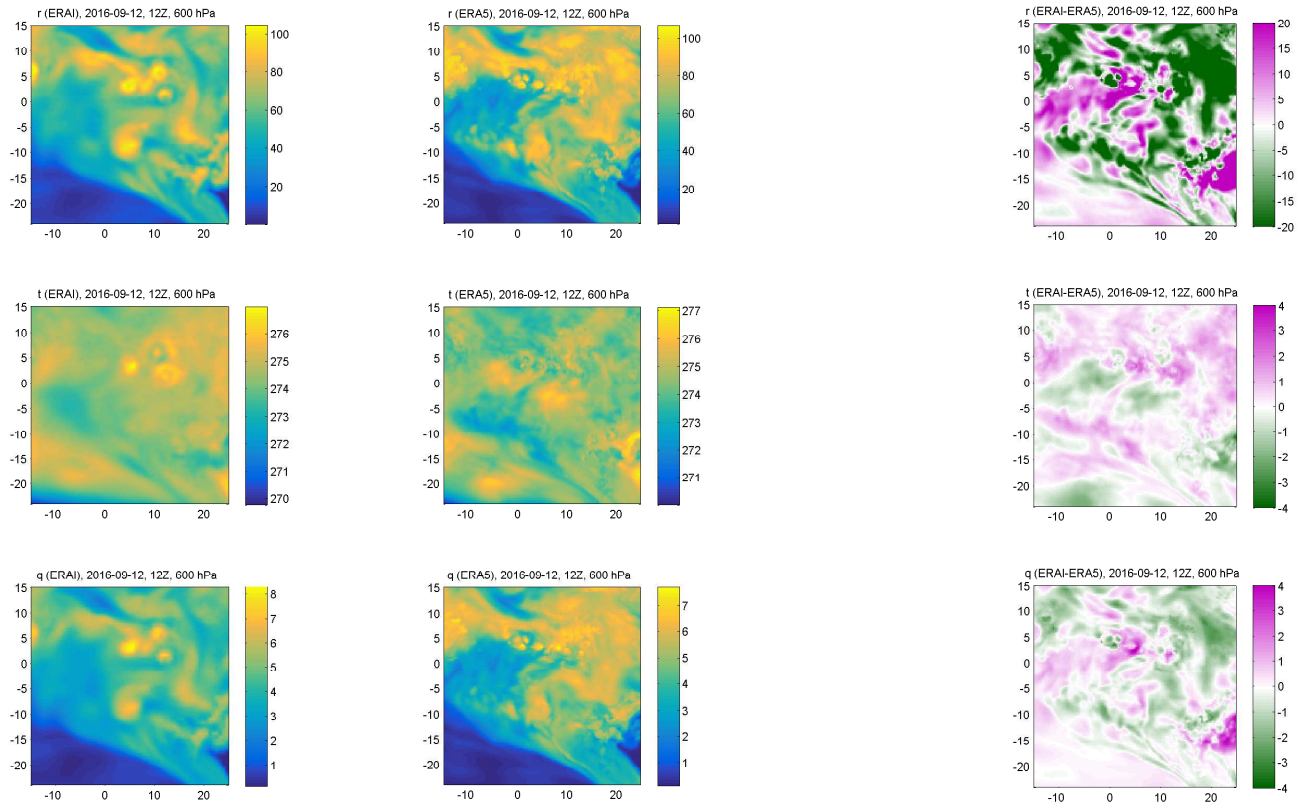

Figure S1. Maps showing an example of relative humidity (r , top), temperature (t , middle), and specific humidity (q , bottom) fields at 600hPa (approximately 4.4km) for 12 September 2016, 12Z for ERA-Interim (left), ERA5 (middle), and the difference between the two (right). While ERA5 shows much higher resolution, both products show areas of high humidity around (10°S , 5°E), and two areas of high temperature appear near the equator in both products, though significantly offset from one another by several degrees of longitude.

Figure S2. Profile from 10 Sep 2016 showing a common difference between ERA-Interim (dotted black line), ERA5 (solid black line), MERRA-2 (dashed purple line), WRF-CAM5 (dashed aqua line), and WRF-Chem (dashed gold line) as compared with the observed values (colored according to CO): namely, that the location of the plume magnitude was often lower in ERA-Interim than either ERA5 or the ORACLES observations. Larger hollow shapes over the aircraft profile indicate the 50-m observed averages around a given reanalysis height, as used in Figure 6

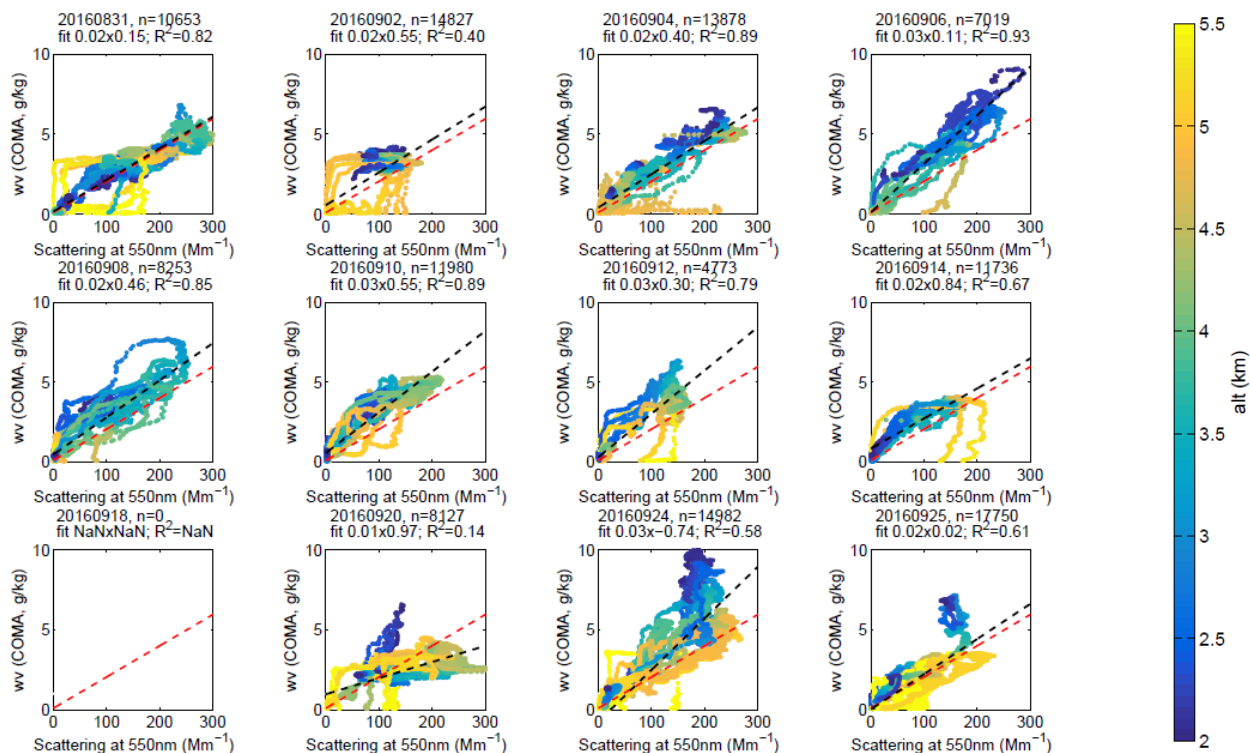

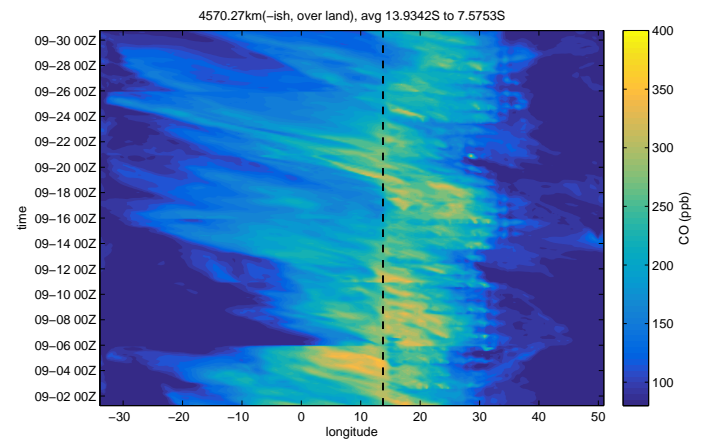

Figure S3. Similar to Figure 3 but here showing scattering at 550nm at actual temperature and pressure (measured by a 3-wavelength TSI Nephelometer) versus water vapor from COMA. The deviations from the coherent line at high altitudes (yellow points) are likely due to a known issue with the TSI Nephelometer in the 2016 deployment, where due to a clogged filter, dead volume within the instrument expanded into the sample volume and caused a delay in the scattering signal response when ascending and flying from polluted into pristine conditions, or when descending and flying from pristine into polluted air (i.e., exiting or entering the top of plume layer). The results are similar for total aerosol extinction (defined as aerosol scattering plus absorption).

(a)

(b)

Figure S4. As in Figure 9, but showing water vapor and CO both from WRF-CAM5. The effects of the reinitialization (i.e., the 3-daily discontinuity) is evident.

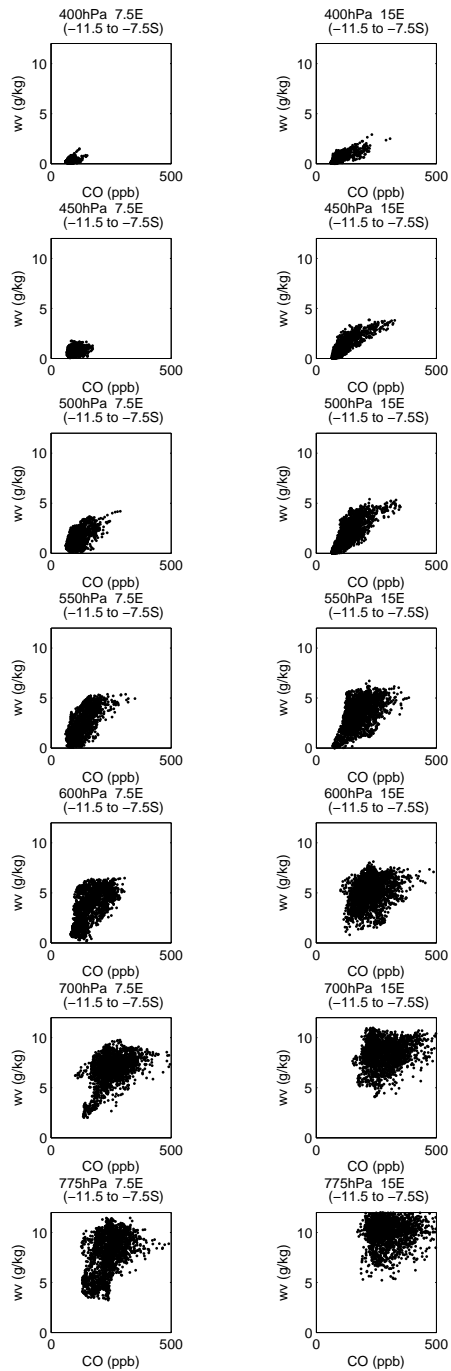

Figure S5. As in Figure 13, for selected altitude levels for the entire month of September (MERRA-2, every 3 hours), showing the dependence of the linear relationship on over-continent mixing between boundary-layer-influenced air and the dry, clean higher troposphere.

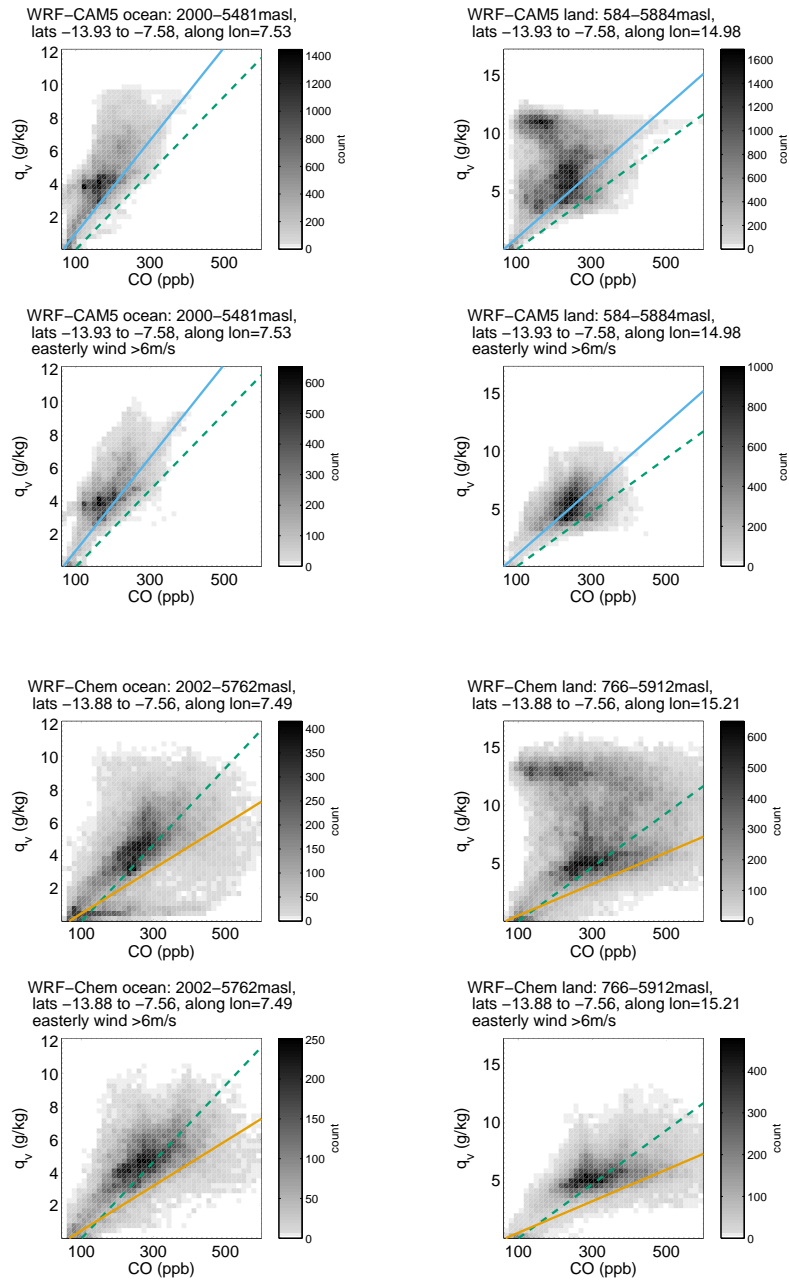

Figure S6. As in Figure 13 but for the two WRF models.

Table S1. Location and time of all aircraft profiles.
