Table S2: LWC sensitivity to LWC threshold method. L^* corresponds to the use of a LWC weight in calculating the mean, rather than a binary mean-over-threshold. Δ is the percentage change from the default calculation using a 0.1 g sm^{-3} threshold.

	Timestamp [UTC s]	L^*	LWC (g sm^{-3}) [Δ] - using variable threshold listed

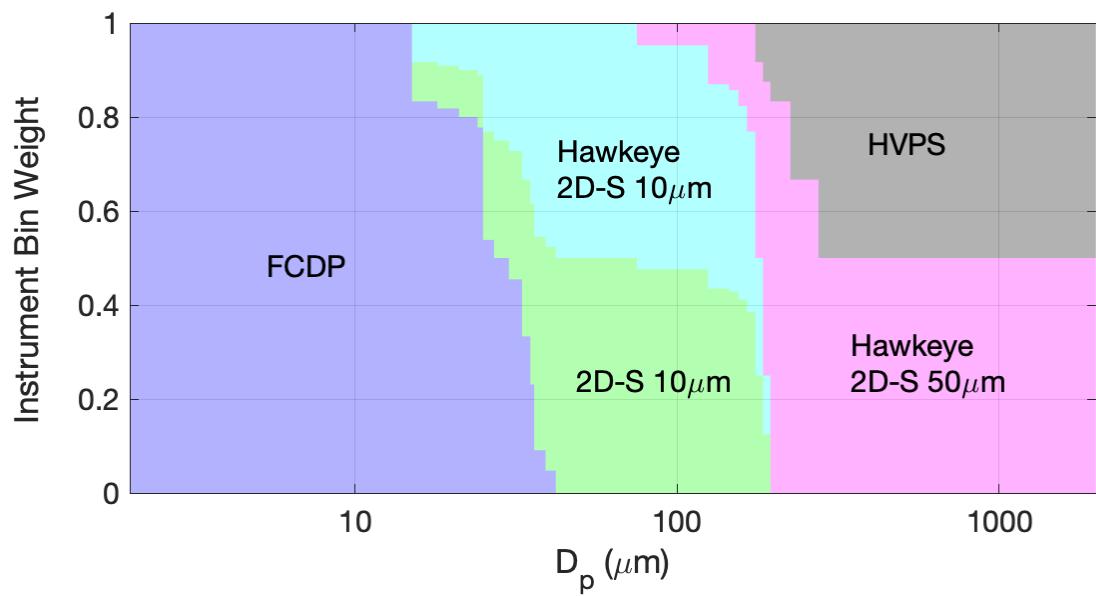

Figure S1: Stitching weight diagram for the estimate of the combined drop size distribution and integrated quantities

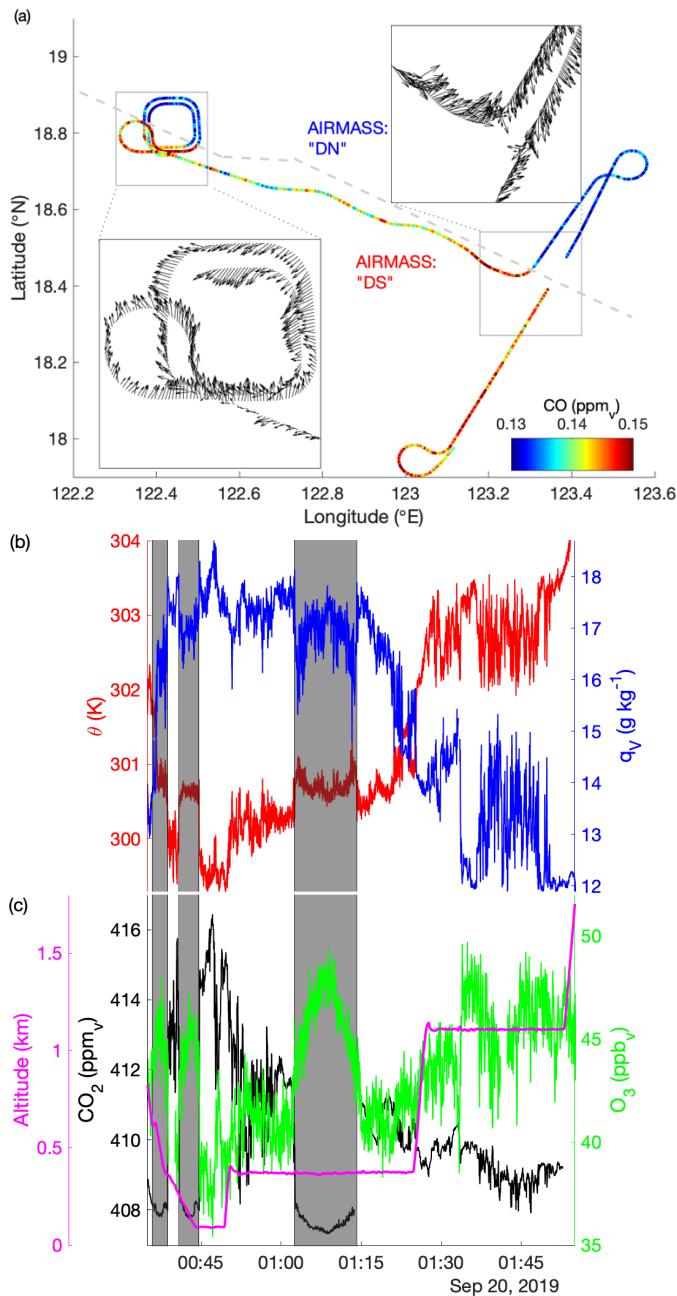

Figure S2: (a) Relationship between horizontal wind anomaly and CO concentration along an airmass boundary sampled downwind of the cloud module in Case I. (b-c) Time series of supporting properties highlighting the cool, moist, O_3 -poor and CO_2 -enhanced downwind-south (DS) airmass.

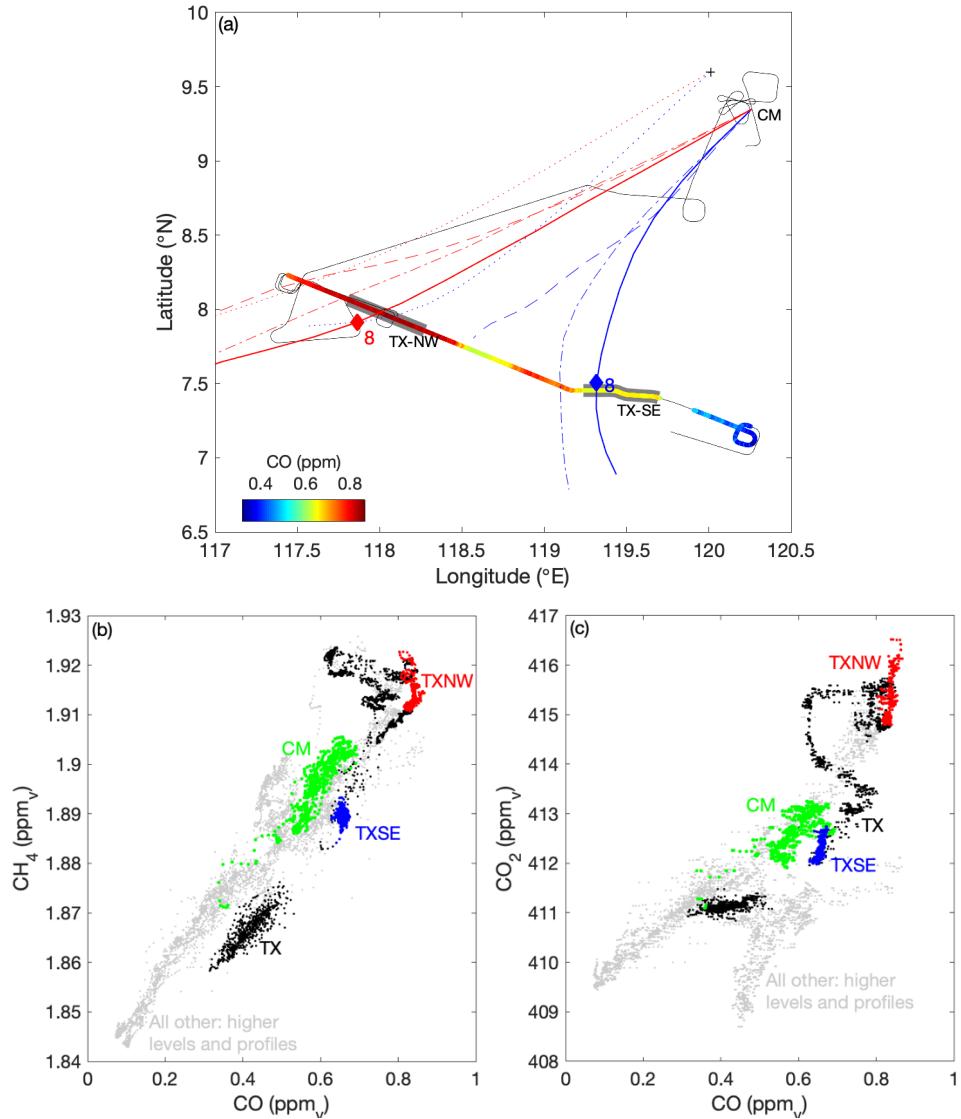

Figure S3: (a) Back trajectory analysis at the cloud module location for Case III with relevant flight segment included [thin black]. Back trajectories were initiated from the center of the sub-cloud [lowest] level leg at the leg altitude [600 m, solid blue] and just above cloud base [1000 m, solid red] at 0400Z September 16. The temporal sensitivity is investigated by repeating trajectories at 00Z [dash] and 08Z [dot-dash]. The spatial sensitivity is investigated by displacing the trajectory end point 0.25° north and 0.25° west [dot]. The diamond markers indicate the projected -8 hour airmass location demonstrating the estimated transit time between the upwind transect and the cloud module. The upwind transect is colored by CO mixing ratio and grey zones represent the regions used to calculate the southeast (TX-SE) and northwest (TX-NW) airmass properties, selected to coincide with the back trajectory uncertainty. (b) and (c) show gas ratios for the entire transect (TX), the TX-NW and TX-SE subsections and the cloud module (CM).

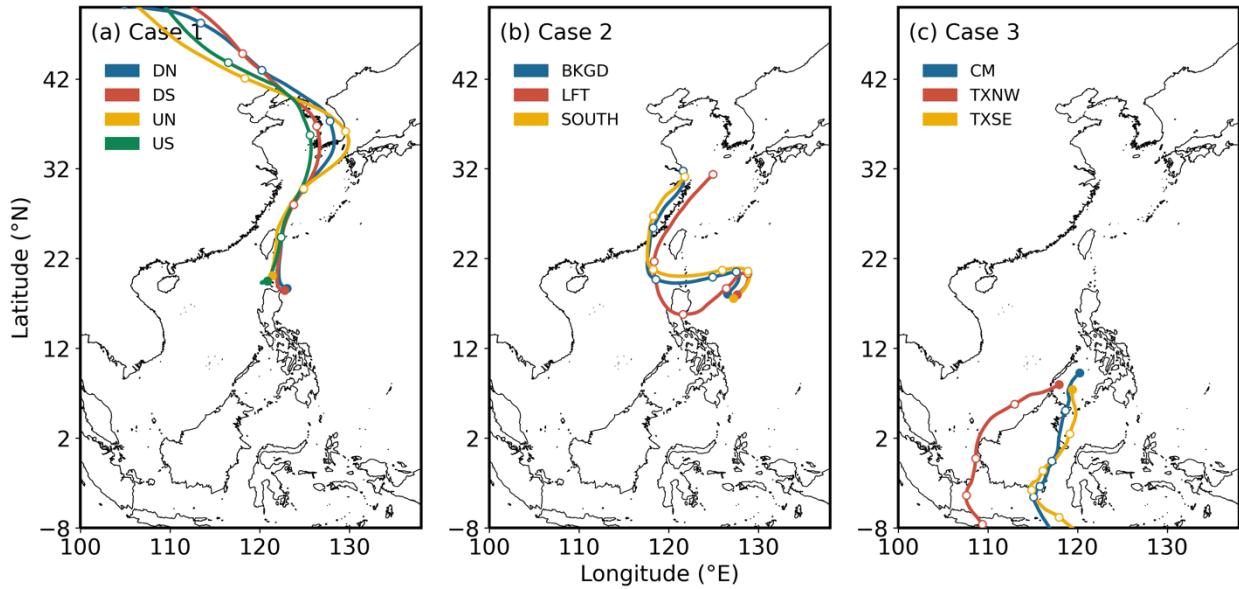

Figure S4: 120 hour back trajectories showing the mean location of the airmasses identified in each case (see text for airmass descriptions). Circles represent intervals of 24 hours. Note that in Case III, the sub-airmasses (TXNW and TXSE) are shown in place of the entire upwind transect (TX) because of the bifurcation of the airmass origin.
