## 1 Data Processing

2 Identified compounds were input into the compound library in the generic form:  $C_cH_hO_oN_nS_s$  (where  
3 c,h,o,n,s represent the number of carbon, hydrogen, oxygen, nitrogen and sulfur atoms  
4 respectively). Where multiple isomers were observed, each isomer was added to the library  
5 independently, based on its retention time (RT). The UHPLC/ESI-HR-MS data for each standard and  
6 ambient sample were analysed using Tracefinder general Quan software (Thermo Fisher Scientific).  
7 Blank subtractions were undertaken for all ambient samples, using a field blank. Tracefinder  
8 extracted compound peak areas from each sample based on the assigned library. The mass  
9 tolerance of the method was set to 3 ppm, with the RT window set to 10 s. The peak tailing factor  
10 was set to 2.0 and the detection algorithm used was ICIS, with a nearest RT detection strategy.  
11 Minimum signal-to-noise (S/N) for a positive identification was set to 3.0. The suitability of the peak  
12 was also assessed for a positive identification, with the peak height at which to compare symmetry  
13 of the left and right side of the peaks set to 40 % and symmetry threshold which is the minimum  
14 percentage difference considered symmetrical set to 70 %.

## 15 Matrix effects

16 The measured signal intensity of the standards in a blank solvent matrix were compared to the  
17 ambient aerosol matrix. A 10  $\mu$ L mixture containing camphorsulfonic acid, 2-MG-OS and 2-MT-OS at  
18 10 ppm was spiked into either 100  $\mu$ L of ambient filter sample extract or into 100  $\mu$ L of blank 50:50  
19 (MeOH:H<sub>2</sub>O) solvent. The samples were run as described above. The matrix effect factors were then  
20 calculated by taking the compound areas from the spiked ambient samples, subtracting the areas of  
21 compounds that were already present in the ambient sample, and then dividing by the compound  
22 areas in the blank matrix. If no matrix effect was present the ratio would equal 1. More details of the  
23 matrix effects associated with the different compound classes and quantification errors are  
24 discussed in the SI. Table S1 shows the ratios across 8 ambient samples collected during both  
25 campaigns, which represent a mixture of high and low PM<sub>2.5</sub> concentrations across different times of  
26 day. 2-MT-OS and 2-MG-OS showed significant matrix effects, with average  $\pm$  SD matrix ratios of  
27  $0.17 \pm 0.06$  and  $0.40 \pm 0.23$ , suggesting 83% and 60% suppressions in signal response.  
28 Camphorsulfonic acid exhibited a much smaller matrix suppression, with an average of  $0.76 \pm 0.16$   
29 suggesting a 24 % suppression, in line with Bryant et al., 2021. The suppression is likely due to the  
30 large numbers of co-eluting inorganic and organic species, reducing the ionisation efficiency of the  
31 marker compounds. Matrix correction factors were applied alongside calibrations to different  
32 compound classes and for compounds eluting at different times.

Table S1. Matrix effect analysis results from 5 filter samples on three different organosulfate standards (CAM-OS – Camphorsulfonic acid, MG-OS – 2-methyl glyceric acid organosulfate, MT-OS – 2-methyl tetrol organosulfate). Alongside PM<sub>2.5</sub> and SO<sub>4</sub> concentrations. The values in bold are the average ratios between a clean matrix and an ambient sample matrix.

Figure S1. Time series variations of measured temperature, planetary boundary layer height (PBLH), relative humidity (RH) and ventilation coefficient (VC, PBLH x wind speed) across pre- (left, a, c, e, g) and post- (right, b, d, f, h) monsoon.

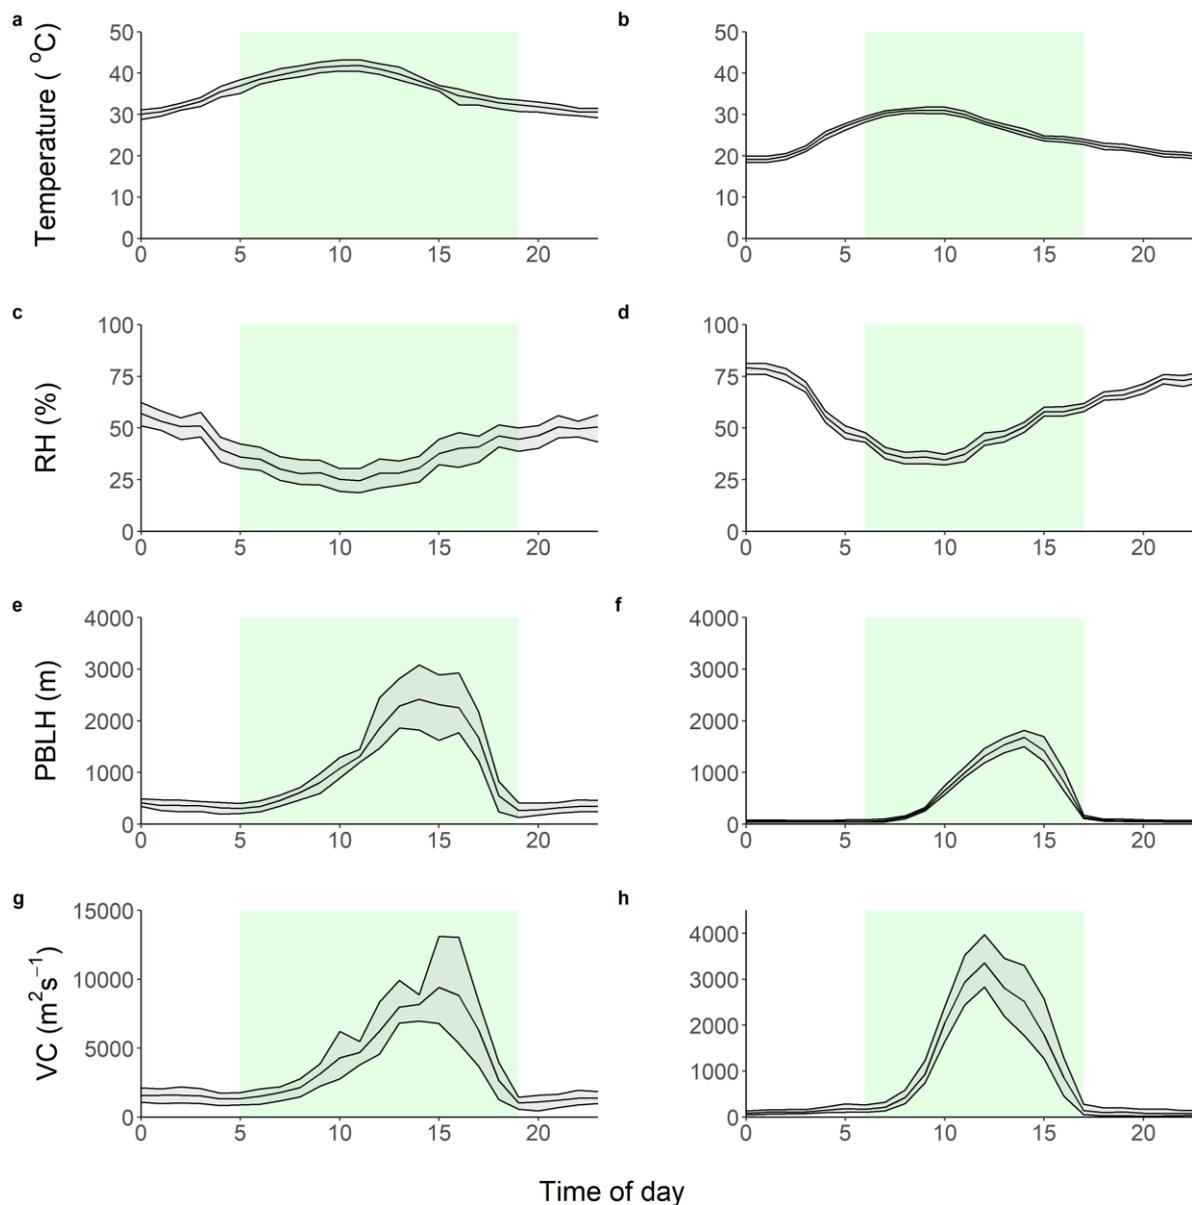

Figure S2. Diurnal variations of temperature, relative humidity (RH), planetary boundary layer height (PBLH) and ventilation coefficient (VC, PBLH \* wind speed) across the pre- (left, a, c, e, g) and post-monsoon (right, b, d, f, h) campaigns. The grey shaded area represents the 95 % confidence interval. The green shaded area represents the times driven by biogenic emissions, as defined by the isoprene diurnals (Figure 3).
