The Chemical Mechanism of MECCA

KPP version: `2.2.3_rs3`

MECCA version: `4.4.0.m1`

Date: August 3, 2022

Batch file: `CCMI2-base-02-tag.bat`

Integrator: `rosenbrock_mz`

Gas equation file: `gas.eqn`

Replacement file: `mim1-CCMI2-base-02`

Selected reactions:
"`(((Tr && (G || Het) && !I) || St) && !Hg)`"

Number of aerosol phases: 0

Number of species in selected mechanism:
Gas phase: 205
Aqueous phase: 0
All species: 205

Number of reactions in selected mechanism:

Gas phase (Gnnn):	265
Aqueous phase (Annn):	0
Henry (Hnnn):	0
Photolysis (Jnnn):	82
Aqueous phase photolysis (PHnnn):	0
Heterogeneous (HETnnn):	12
Equilibria (EQnn):	0
Isotope exchange (IEXnnn):	0
Tagging equations (TAGnnn):	0
Dummy (Dnn):	0
All equations:	359

Table 1: Gas phase reactions

General notes

Three-body reactions

Rate coefficients for three-body reactions are defined via the function $\texttt{k\_3rd}(T, M, k_0^{300}, n, k_{\mathrm{inf}}^{300}, m, f_c)$. In the code, the temperature T is called $\texttt{temp}$ and the concentration of "air molecules" M is called $\texttt{cair}$. Using the auxiliary variables $k_0(T)$, $k_{\mathrm{inf}}(T)$, and k_{ratio}, $\texttt{k\_3rd}$ is defined as:

$$k_0(T) = k_0^{300} \times \left(\frac{300\mathrm{K}}{T}\right)^n \tag{1}$$

$$k_{\mathrm{inf}}(T) = k_{\mathrm{inf}}^{300} \times \left(\frac{300\mathrm{K}}{T}\right)^m \tag{2}$$

$$k_{\mathrm{ratio}} = \frac{k_0(T)M}{k_{\mathrm{inf}}(T)} \tag{3}$$

$$\texttt{k\_3rd} = \frac{k_0(T)M}{1 + k_{\mathrm{ratio}}} \times f_c^{\left(\frac{1}{1+(\log_{10}(k_{\mathrm{ratio}}))^2}\right)} \tag{4}$$

A similar function, called $\texttt{k\_3rd\_iupac}$ here, is used by Wallington et al. (2018) for three-body reactions. It has the same function parameters as $\texttt{k\_3rd}$ and it is defined as:

$$k_0(T) = k_0^{300} \times \left(\frac{300\mathrm{K}}{T}\right)^n \tag{5}$$

$$k_{\mathrm{inf}}(T) = k_{\mathrm{inf}}^{300} \times \left(\frac{300\mathrm{K}}{T}\right)^m \tag{6}$$

$$k_{\mathrm{ratio}} = \frac{k_0(T)M}{k_{\mathrm{inf}}(T)} \tag{7}$$

$$N = 0.75 - 1.27 \times \log_{10}(f_c) \tag{8}$$

$$\texttt{k\_3rd\_iupac} = \frac{k_0(T)M}{1 + k_{\mathrm{ratio}}} \times f_c^{\left(\frac{1}{1+(\log_{10}(k_{\mathrm{ratio}})/N)^2}\right)} \tag{9}$$

Structure-Activity Relationships (SAR)

Some unmeasured rate coefficients are estimated with structure-activity relationships, using the following parameters and substituent factors:

k for H-abstraction by OH in $\mathrm{cm^{-3}s^{-1}}$	
k_p	$4.49 \times 10^{-18} \times (T/\mathrm{K})^2 \exp(-320\,\mathrm{K}/T)$
k_s	$4.50 \times 10^{-18} \times (T/\mathrm{K})^2 \exp(253\,\mathrm{K}/T)$
k_t	$2.12 \times 10^{-18} \times (T/\mathrm{K})^2 \exp(696\,\mathrm{K}/T)$
k_ROHRO	$2.1 \times 10^{-18} \times (T/\mathrm{K})^2 \exp(-85\,\mathrm{K}/T)$
k_CO2H	$0.7 \times k_{\mathrm{CH_3CO_2H+OH}}$
k_ROOHRO	$0.6 \times k_{\mathrm{CH_3OOH+OH}}$
f_alk	1.23
f_sOH	3.44
f_tOH	2.68
f_sOOH	8.
f_tOOH	8.
f_ONO2	0.04
f_CH2ONO2	0.20
f_cpan	0.25
f_allyl	3.6
f_CHO	0.55
f_CO2H	1.67
f_CO	0.73
f_O	8.15
f_pCH2OH	1.29
f_tCH2OH	0.53

k for OH-addition to double bonds in $\mathrm{cm^{-3}s^{-1}}$	
k_adp	$4.5 \times 10^{-12} \times (T/300\,\mathrm{K})^{-0.85}$
k_ads	$1/4 \times (1.1 \times 10^{-11} \times \exp(485\,\mathrm{K}/T)+$
	$1.0 \times 10^{-11} \times \exp(553\,\mathrm{K}/T))$
k_adt	$1.922 \times 10^{-11} \times \exp(450\,\mathrm{K}/T) - k_{\mathrm{ads}}$
k_adsecprim	3.0×10^{-11}
k_adtertprim	5.7×10^{-11}
a_PAN	0.56
a_CHO	0.31
a_COCH3	0.76
a_CH2OH	1.7
a_CH2OOH	1.7
a_COH	2.2
a_COOH	2.2
a_CO2H	0.25
a_CH2ONO2	0.64

RO$_2$ self and cross reactions

The self and cross reactions of organic peroxy radicals are treated according to the permutation reaction formalism as implemented in the MCM (Rickard and Pascoe, 2009), as decribed by Jenkin et al. (1997). Every organic peroxy radical reacts in a pseudo-first-order reaction with a rate constant that is expressed as $k^{\mathrm{1st}} = 2 \times \sqrt{k_{\mathrm{self}} \times \texttt{k\_CH3O2}} \times [\mathrm{RO_2}]$ where $k_{\mathrm{self}} = $ second-order rate coefficient of the self reaction of the organic peroxy radical, $\texttt{k_CH3O2} = $ second-order rate coefficient of the self reaction of $\mathrm{CH_3O_2}$, and $[\mathrm{RO_2}] = $ sum of the concentrations of all organic peroxy radicals.

Specific notes

G1002a: The path leading to 2 $O(^3P) + O_2$ results in a null cycle regarding odd oxygen and is neglected.

G2110: The rate coefficient is: `k_HO2_HO2 = (3.0E-13*EXP(460./temp)+2.1E-33*EXP(920./temp) *cair)*(1.+1.4E-21*EXP(2200./temp)*C(ind_H2O))`.

G3109: The rate coefficient is: `k_NO3_NO2 = k_3rd(temp,cair,2.4E-30,3.0,1.6E-12,-0.1,0.6)`.

G3110: The rate coefficient is defined as backward reaction divided by equilibrium constant.

G3203: The rate coefficient is: `k_NO2_HO2 = k_3rd(temp,cair,1.9E-31,3.4,4.0E-12,0.3,0.6)`.

G3206: The rate coefficient is: `k_HNO3_OH = 1.32E-14 * EXP(527/temp) + 1 / ( 1 / (7.39E-32 * EXP(453/temp)*cair) + 1 / (9.73E-17 * EXP(1910/temp)) )`

G3207: The rate coefficient is defined as backward reaction divided by equilibrium constant.

G4103: Sander et al. (2006) recommend a zero product yield for HCHO.

G4109: The same temperature dependence assumed as for $CH_3CHO+NO_3$. At 298 K, $k = 5.8 \times 10^{-16}$.

G4201: The product distribution is from Rickard and Pascoe (2009), after substitution of the Criegee intermediate by its decomposition products.

G4206: The product C_2H_5OH, which reacts only with OH, is substituted by its degradation products ≈ 0.1 $HOCH_2CH_2O_2 + 0.9 \, CH_3CHO + 0.9 \, HO_2$.

G4207: Same value as for G4107

G4213: The rate coefficient is: `k_CH3CO3_NO2 = k_3rd(temp,cair,9.7E-29,5.6,9.3E-12,1.5,0.6)`.

G4221: The rate coefficient is `k_PAN_M = k_CH3CO3_NO2/9.E-29*EXP(-14000./temp)`, i.e. the rate coefficient is defined as backward reaction divided by equilibrium constant.

G4307: Same value as for G4107

G4315: Same value as for G4107

G4401: Same value as for G4306

G4402: Same value as for G4304

G4403: Same value as for G4305

G4404: Same value as for G4107

G4414: Same value as for G4304

G4415: Same value as for G4305

G4416: Same value as for G4107

G4419: Same value as for G4221

G6103: The rate coefficient is defined as backward reaction divided by equilibrium constant.

G6204: At low temperatures, there may be a minor reaction channel leading to O_3+HCl. See Finkbeiner et al. (1995) for details. It is neglected here.

G6402: The initial products are probably HCl and CH_2OOH (Atkinson et al., 2006). It is assumed that CH_2OOH dissociates into HCHO and OH.

G6405: Sander et al. (2006), but simplified shortcut to release all Cl

G7302: The rate coefficient is: `k_BrO_NO2 = k_3rd(temp,cair,5.2E-31,3.2,6.9E-12,2.9,0.6)`.

G7303: The rate coefficient is defined as backward reaction (Atkinson et al., 2007) divided by equilibrium constant (Orlando and Tyndall, 1996).

G7407: It is assumed that the reaction liberates all Br atoms. The fate of the carbon atom is currently not considered.

G7408: It is assumed that the reaction liberates all Br atoms. The fate of the carbon atom is currently not considered.

G7605: Same value as for G7408: CH_2Br_2+OH assumed. It is assumed that the reaction liberates all

Br and all Cl. The fate of the carbon atom is currently not considered.

G7606: Same value as for G7408: CH_2Br_2+OH assumed. It is assumed that the reaction liberates all Br atoms and also Cl. The fate of the carbon atom is currently not considered.

G7607: It is assumed that the reaction liberates all Br atoms and also Cl. The fate of the carbon atom is currently not considered.

G9400a: For the abstraction path, the assumed reaction sequence (omitting H_2O and O_2 as products) according to Yin et al. (1990) is:

$$
\begin{aligned}
DMS + OH &\rightarrow CH_3SCH_2 \\
CH_3SCH_2 + O_2 &\rightarrow CH_3SCH_2OO \\
CH_3SCH_2OO + NO &\rightarrow CH_3SCH_2O + NO_2 \\
CH_3SCH_2O &\rightarrow CH_3S + HCHO \\
CH_3S + O_3 &\rightarrow CH_3SO \\
CH_3SO + O_3 &\rightarrow CH_3SO_2 \\
\hline
DMS + OH + NO + 2O_3 &\rightarrow CH_3SO_2 + HCHO + NO_2
\end{aligned}
$$
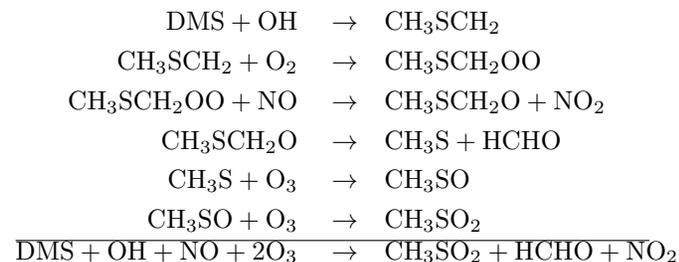

Neglecting the effect on O_3 and NO_x, the remaining reaction is:

$$DMS + OH + O_3 \rightarrow CH_3SO_2 + HCHO$$

.
G9400b: For the addition path, the rate coefficient is: `k_DMS_OH = 1.0E-39*EXP(5820./temp)*C(ind_O2) / (1.+5.0E-30*EXP(6280./temp)*C(ind_O2))`.

PH (aqueous)				

General notes

j-values are calculated with an external module (e.g., JVAL) and then supplied to the MECCA chemistry.

Values that originate from the Master Chemical Mechanism (MCM) by Rickard and Pascoe (2009) are translated according in the following way:
j(11) → jx(ip_COH2)
j(12) → jx(ip_CHOH)
j(15) → jx(ip_HOCH2CHO)
j(18) → jx(ip_MACR)
j(22) → jx(ip_ACETOL)
j(23)+j(24) → jx(ip_MVK)
j(31)+j(32)+j(33) → jx(ip_GLYOX)
j(34) → jx(ip_MGLYOX)

j(41) → jx(ip_CH3OOH)
j(53) → j(isopropyl nitrate)
j(54) → j(isopropyl nitrate)
j(55) → j(isopropyl nitrate)
j(56)+j(57) → jx(ip_NOA)

Specific notes

J4302: It is assumed that J(CH$_3$COCH$_2$OH) is 0.074 times that of J4101b.

J4304: It is assumed that J(CH$_3$COCH$_2$O$_2$H) is the same as J(CH$_3$OOH).

J4306: Following von Kuhlmann et al. (2003), we use J(iC$_3$H$_7$ONO$_2$) = 3.7*jx(ip_PAN).

J4402: It is assumed that J(MVKOOH) is the same as J(CH$_3$OOH).

J4405: It is assumed that J(BIACET) is 2.15 times larger than J(MGLYOX), consistent with the photolysis rate coefficients used in the MCM (Rickard and Pascoe, 2009).

J4407: It is assumed that J(MPAN) is the same as J(PAN).

J4500: It is assumed that J(ISOOH) is the same as J(CH$_3$OOH).

J7301: The quantum yields are recommended by Burkholder et al. (2015) for $\lambda > 300$nm and used here for the entire spectrum.

J6500dc01: OKAY!

Table 3: Reversible (Henry's law) equilibria and irreversible ("heterogenous") uptake

#	labels	reaction	rate coefficient	reference

General notes

The forward (`k_exf`) and backward (`k_exb`) rate coefficients are calculated in subroutine `mecca_aero_calc_k_ex` in the file `messy_mecca_aero.f90` using accommodation coefficients and Henry's law constants from chemprop (see `chemprop.pdf`).

For uptake of X (X = N_2O_5, $ClNO_3$, or $BrNO_3$) and subsequent reaction with H_2O, Cl^-, and Br^- in H3201, H6300, H6301, H6302, H7300, H7301, H7302, H7601, and H7602, we define:

$$k_{\text{exf}}(X) = \frac{k_{\text{mt}}(X) \times \text{LWC}}{[H_2O] + 5 \times 10^2[Cl^-] + 3 \times 10^5[Br^-]}$$

Here, k_{mt} = mass transfer coefficient, and LWC = liquid water content of the aerosol. The total uptake rate of X is only determined by k_{mt}. The factors only affect the branching between hydrolysis and the halide reactions. The factor 5×10^2 was chosen such that the chloride reaction dominates over hydrolysis at about $[Cl^-]$ > 0.1 M (see Fig. 3 in Behnke et al. (1997)), i.e. when the ratio $[H_2O]/[Cl^-]$ is less than 5×10^2. The ratio $5 \times 10^2 / 3 \times 10^5$ was chosen such that the reactions with chloride and bromide are roughly equal for sea water composition (Behnke et al., 1994). These ratios were measured for uptake of N_2O_5. Here, they are also used for $ClNO_3$ and $BrNO_3$.

Table 4: Heterogeneous reactions

General notes

Heterogeneous reaction rates are calculated with an external module (e.g., MECCA_KHET) and then supplied to the MECCA chemistry (see `www.messy-interface.org` for details)
