

2.6Tg and 1.8Tg, respectively; better implementation of current control policies will reduce SO<sub>2</sub>, NO<sub>x</sub> and PM<sub>10</sub> emission by 2.9Tg, 1.8Tg, and 1.4Tg, respectively; strict emission standards will reduce SO<sub>2</sub>, NO<sub>x</sub> and PM<sub>10</sub> emissions by 3.2Tg, 3.9Tg, and 1.7Tg, respectively. Under the PC[2] scenario, SO<sub>2</sub> and PM<sub>10</sub> emissions will decrease by 18% and 38%, while NO<sub>x</sub> and VOC emissions will increase by 3% and 8%, compared to that in 2005. Future air quality in China was simulated using the Community Multi-scale Air Quality Model (CMAQ). Under REF[0] emissions, the surface concentrations of SO<sub>2</sub>, NO<sub>2</sub>, hourly maximum ozone in summer, PM<sub>2.5</sub>, total sulfur and nitrogen depositions will increase by 28%, 41%, 8%, 8%, 19% and 25%, respectively, over east China. Under the PC[2] emission scenario, the surface concentrations of SO<sub>2</sub>, PM<sub>2.5</sub>, total sulfur depositions will decrease by 18%, 16% and 15%, respectively, and the surface concentrations of NO<sub>2</sub>, nitrate, hourly maximum ozone in summer, total nitrogen depositions will be kept as 2005 level, over east China. The individual impacts of SO<sub>2</sub>, NO<sub>x</sub>, NH<sub>3</sub>, NMVOC and primary PM emission changes on ozone and PM<sub>2.5</sub> concentrations have been analyzed using sensitivity analysis. The results suggest that NO<sub>x</sub> emission control need to be enhanced during the summertime to obtain both ozone and PM<sub>2.5</sub> reduction benefits. NH<sub>3</sub> emission controls should also be considered in order to reduce both nitrate and total nitrogen deposition in the future.

## 1. Introduction

With the fast growth of the domestic economy and urbanization in China, the emissions of air pollutants from coal combustion, industrial production, and transport have been increasing at an unprecedented rate over the last decade. From 1995 to 2005, the annual growth rates of energy consumption, cement production, steel production, and the vehicle population, were 10%, 24%,

1 12%, and 10%, respectively. The observations from satellite remote sensing indicate that NO<sub>x</sub>  
2 emissions in the Central and East China have accelerated by a factor of 2 during 2000~2006  
3 ([Richter et al., 2005](#)). There is evidence that anthropogenic emissions of air pollutants in China are  
4 influencing not only local and regional, but also the global atmospheric environment ([Wild and](#)  
5 [Akimoto, 2001](#); [Liang et al., 2004](#); [Dickerson et al., 2007](#)). A better understanding of the emissions  
6 of air pollutants and their impact on air quality is therefore of great interest.

7 In 2009, the total energy consumption in China reached 3.1 billion tons of coal equivalents  
8 (tce), of which 69% is from coal ([NBSC, 2010](#)). China has overtaken the United States to become  
9 the world's largest energy user. What is more important is that the growth of energy consumption  
10 will continue into future because the energy consumption on a per capita basis is still only about  
11 one-third of the OECD average. Therefore, there are strong indications that emissions of air  
12 pollutants will keep increasing in the next decade. Future changes in air quality will be affected  
13 strongly by the expected changes in anthropogenic emissions, which are controlled by economic  
14 growth, environmental policy, and the future implementation of emissions controls. In light of this  
15 situation, the projections of future emissions are essential to designing cost-effective mitigation  
16 strategies and to understanding how the emissions affect the future air quality in China and Asia  
17 ([Dentener et al. 2006](#); [Unger et al., 2006](#)).

18 Projections of Chinese (as part of Asia) emissions from fuel combustion and industrial  
19 sources have been made by [van Aardenne et al. \(1999\)](#) for NO<sub>x</sub>, [Streets and Waldhoff \(2000\)](#) for  
20 SO<sub>2</sub>, NO<sub>x</sub>, and CO, [Klimont et al. \(2001\)](#) for SO<sub>2</sub>, NO<sub>x</sub>, NH<sub>3</sub>, and NMVOC, and [Ohara et al \(2007\)](#)  
21 for SO<sub>2</sub>, NO<sub>x</sub>, CO, NMVOC, black carbon (BC), and organic carbon (OC). Some studies have also  
22 forecast surface ozone levels over East Asia for the year 2020, indicating that NO<sub>x</sub> (NO<sub>x</sub> = NO +

1 NO<sub>2</sub>) and ozone would be a potential issue (Yamaji et al., 2008). These early projections suffered  
2 from poor data availability and were too optimistic about the pace of the introduction and  
3 effectiveness of environmental legislation. These projections also underestimated the economic  
4 growth experienced in the last decade in China (Klimont et al., 2009).

5         Based on the most recent development plan for key industries and on new information on  
6 local emission factors in China, this paper presents possible emission scenarios for SO<sub>2</sub>, NO<sub>x</sub>,  
7 non-methane volatile organic compounds (NMVOCs), NH<sub>3</sub> and primary particles (PM), and the  
8 potential impacts of emission changes on the regional air quality in China for the year 2020.  
9 Simulations on 2005 baseline and 2020 future emission scenarios have been conducted and  
10 analyzed using the Community Multi-scale Air Quality Model (CMAQ) for four months (January,  
11 April, July, and October). The next section describes the methodology used for the energy  
12 consumption forecast, the air pollution control legislation considered and the corresponding future  
13 emission scenarios. Section 3 presents the model output surface concentrations of SO<sub>2</sub>, NO<sub>2</sub>, fine  
14 particles, ozone, total sulfur and nitrogen deposition based on emissions in 2005 (the base year) and  
15 in 2020. Conclusions and recommendations for future air pollution control policies are provided in  
16 Section 4.

## 17 **2. Projection of SO<sub>2</sub>, NO<sub>x</sub>, PM, NMVOC and NH<sub>3</sub> Emissions in China**

18         The regions studied covered 31 Provinces, autonomous regions and municipalities over  
19 mainland China. Hong Kong, Macao and Taiwan were not included. Their emissions in 2020 are  
20 assumed as same as the 2005 baseline scenario, which are taken from the INDEX-B datasets (Zhang  
21 et al, 2009). SO<sub>2</sub>, NO<sub>x</sub>, and PM with different size fractions (TSP, PM<sub>10</sub>, and PM<sub>2.5</sub>), NMVOC and  
22 NH<sub>3</sub> were the targeted pollutant species. All data were at the provincial level. For a given Province  $i$ ,

year  $y$ , and pollutant  $n$  considered in this paper, the emissions were calculated using the following equations:

$$E_{n,y} = \sum_{i,k,l} A_{i,k,l,y} \sum_m [ef_{i,k,l,n} (1 - \eta_{i,k,m,n}) X_{i,k,l,m,y}] \quad (0 < X \leq 1) \quad (E1)$$

$$E_{n,y} = \sum_{i,k,l} A_{i,k,l,y} ef_{i,k,l,n} \quad (X=0) \quad (E2)$$

where,  $i$  represents the Province (administrative region);  $k$  represents the economic sector or combustion technology type;  $l$  represents the fuel type (if relevant for a specific  $k$ );  $m$  represents the abatement technology type;  $E$  is the national annual emissions;  $A$  is the activity level (e.g. fuel consumption, industrial production, amount of biomass burned on-field);  $ef$  is the uncontrolled emission factor;  $\eta$  is the reduction efficiency of the abatement technology; and  $X$  is the penetration of the abatement measure  $m$  expressed as a percentage of total activity  $A$ .

To improve the emission estimates, data for emission factors are collected from the field measurements of Tsinghua University and other published results, as described in section 2.2. Unit-based methodology is applied to estimate emissions from large point sources including coal-fired power plants, iron and steel plants, and cement plants (Zhao et al., 2008; Lei et al., 2008). Detailed local emission information aggregated from the bottom-up investigation of individual power plants, heating boilers, and industries in Beijing, Yangtze River Delta and Pearl River Delta are also incorporated into the national emission inventory (Li et al., 2008; Zheng et al., 2009; Wang et al., 2010). A detailed description about the 2005 base year emission inventory is given in Xing et al. (2010).

## 2.1 Projection of Energy Consumption

The energy consumption level was estimated in collaboration between the research groups at International Institute for Applied Systems Analysis (IIASA) in Laxenburg (Austria), Tsinghua

1 University and Energy Research Institute (ERI) in Beijing (China) ([Amann et al., 2008](#)).

2         The new projection are based in the provincial level, reflects current Chinese expectations  
3 with regard to the population projections from the National Population Development Strategy and  
4 the national development targets for renewable energy sources in the ‘11<sup>th</sup> Five-Year Plan’. The  
5 energy forecast (i.e., energy demand, energy efficiency estimation and technology selection) were  
6 estimated by IPAC-AIM/local model developed by ERI ([Jiang and Hu, 2006](#); [Jiang et al., 2009](#)), a  
7 bottom-up model with sectors classification and more than 100 technologies. The model searches  
8 for the least-cost technology mix to meet the given energy service demand (including five major  
9 sectors such as industry, agriculture, service, residence, and transportation, which are further  
10 divided into sub-sectors). The up-to-date information on these technologies was collected from  
11 large number of literature. The details about the forecast of future activities are given as follows.

## 12 (1) Population

13         The national population projections for the year 2010 to 2020 were completely adopted  
14 from the Research Report on National Population Development Strategy ([NPDSR, 2007](#)), i.e., 1.36  
15 and 1.45 billion in 2010 and 2020. The provincial populations were forecasted using the historical  
16 data from 1995 to 2005 through the logistic regression method. Minor adjustment was conducted to  
17 make the total of provincial populations to be consistent with the national population.

## 18 (2) Gross Domestic Product (GDP, in year 2000 prices)

19         The provincial GDP growth rates from 2006 to 2010 were attained from the 11<sup>th</sup> five-year  
20 plan enacted by the local provincial governments ([http://www.gov.cn/test/2006-07/25/](http://www.gov.cn/test/2006-07/25/content_344715.htm)  
21 [content\\_344715.htm](http://www.gov.cn/test/2006-07/25/content_344715.htm), in Chinese). The provincial GDP growth rates from 2010 to 2020 were  
22 forecast using the logistic regression method according to the historical data from 1996 to 2005.

The average annual growth rate of national GDP was calculated from the provincial data, which was in line with the Reference Scenario in International Energy Agency (IEA) report, i.e., 7.7% during 2005-2015 and 6% over 2015-2020 (IEA, 2007).

### (3) Activity data

We developed two energy scenarios, a reference scenario (REF) which was based on current development trends, and a policy scenario (PC) which assumed that more sustainable energy development strategies would be adopted in the future. Baseline scenario gives a basic trend to describe future economic activities. Only existing legislations on energy and environment will be implemented. Various energy and emission control policies are assumed for the policy scenario. In the policy scenario, policies on energy conservation, renewable energy will be widely adopted by both regulation and financial incentives. Economic structure change is also considered. However, the application of abatement technologies is assumed same across all provinces in this study. Scenario assumptions and key macroeconomic parameters are given in Table 1.

Projection of electricity generation considers the use of different energy and technologies. The development of renewable energy sources followed the national targets in the 11<sup>th</sup> Five-Year Plan (NDRC, 2008a). The future development of hydro power, nuclear power and other renewable resources, the improvement of thermal efficiency, as well as the fuel structure have been considered in the model. The annual nuclear generation will be 260-280 billion kWh in 2020, according to the ‘long-term development plan of nuclear power’ reported by NDRC (NDRC, 2007). The hydro power will be developed in west China. The west-east gas transmitting project will promote natural gas power plants in the future. But the coal will still be the dominant fuel, accounting for 95.3% and 93.6% of thermal power plants in 2020REF and 2020PC, respectively. The power generation

1 technologies include sub-critical units with a thermal efficiency of 30-36%, super-critical units with  
2 a thermal efficiency of 41%, ultra-supercritical units with a thermal efficiency of 43%, and IGCC  
3 (Integrated Gasification Combined Cycle) with a thermal efficiency of 45-55%. Before 2005,  
4 sub-critical units are the dominant technology. Super-critical units are widely applied since 2005.  
5 Ultra-supercritical units and IGCC will be promoted in the next five years. Closing the small units  
6 is another policy to improve the energy efficiency of power sector. Considering the promotion new  
7 technologies, the thermal efficiencies are assumed to increase to 37.5% in 2020 REF and 38.5% in  
8 2020 PC scenario.

9         Primary energy demand is related to energy service demand of each subsector driven by  
10 the socio-economic growth (i.e., population, GDP, lifestyle, etc), and also influenced by the  
11 technology progress, energy efficiency as well as the transition of energy and industry structure.

12         For industrial sectors, in general, the comprehensive energy consumption will reach the  
13 levels of developed countries in 2020. The comprehensive energy consumption in steel production,  
14 non-ferrous metal smelting, ethylene, ammonia synthesis, and cement production will decrease by  
15 18%, 7%, 29%, 27% and 33% respectively in 2020, compared to that in 2000, according to the  
16 ‘energy-saving in long-term and special program’ reported by NRDC ([NRDC, 2004](#)). The ratio of  
17 coal in energy structure will decrease, and the ratio of natural gas and electricity will slightly  
18 increase. The ratio of Circulating Fluidized-Bed (CFB) boiler used in industry will increase from  
19 10% in 2005 to 15% in 2020, since CFB is more efficient and emits less SO<sub>2</sub>/NO<sub>x</sub> than grate boiler.

20         For domestic sources, along with the increase of the per capita income of rural residents,  
21 cleaner fuel will be promoted. In developed regions (e.g., Beijing, Tianjin, Shanghai), coal will be  
22 replaced by nature gas and electricity. In less developed regions where biomass is the major energy

1 type, the biomass is going to be replaced by coal or gas and electricity. According to the  
2 ‘energy-saving in long-term and special program’, energy saving in constructions, commercial and  
3 residential sectors has also been considered, including design of energy saving building and  
4 energy-saving appliances promotion.

5 For mobile sources, the vehicle populations of truck, car, and motor cycle, as well as  
6 passenger or freight traffic volume of inland water and railroad, are driven by the socio-economic  
7 growth. The energy consumptions in transportation sector are also influenced by the changes of  
8 vehicle types and fuel economy. Those parameters are mainly referred to [He et al. \(2005\)](#), [Wang et al. \(2007\)](#) and [IEA \(2007\)](#). There is a continuous growth trend of larger trucks for long-distance  
9 freight transportation and a trend in rapid growth in light and mini vehicle fleets, while the  
10 medium-size trucks will decline greatly. Besides, the share of diesel vehicles in the Chinese vehicle  
11 fleet will increase, since diesel vehicles have better fuel economy than gasoline vehicles. Passenger  
12 car ownership will experience exploding growth due to rapid growth of private vehicles. To  
13 improve the fuel economy, Chinese government released a series of energy consumption standards  
14 for vehicles, such as the ‘limits of fuel consumption for passenger cars’ in 2004, ‘limits of fuel  
15 consumption for light duty commercial vehicles’ in 2007, ‘low-speed goods vehicles—limits and  
16 measurement methods for fuel consumption’ and ‘Tri-wheel vehicles—limits and measurement  
17 methods for fuel consumption’ in 2008. Fuel economy of car, truck, motorcycle, and agriculture  
18 transport machine will increase by 30%/40%, 25%/36%, 30%/36%, and 15%/23% in 2020REF/PC  
19 scenarios, compared to that in 2005. According to the ‘energy-saving in long-term and special  
20 program’ reported by [NRDC \(2004\)](#), the comprehensive energy consumption in railroad will reduce  
21 from 9.65tce/(Mt.km) in 2005 to 9.00 tce/(Mt.km) in 2020.  
22

1           The industrial process sector is forecast based on the population and GDP projections. The  
2   logistic model was used to forecast the total industrial production in China. The industrial  
3   production was considered to be related to the industrial development level represented by the  
4   industrial added value (Jiang and Hu, 2006). The model parameters were solved from the historical  
5   data from 1996-2005. The quantity of provincial industrial product was forecast by their respective  
6   ratios in the total industrial product. The renovation of technology has been considered. According  
7   to the ‘Suggestions on speeding up the cement industry structure adjustment’ released by NRDC  
8   (2006), the advanced precalcining kilns will take up 70% of total cement production by 2010. The  
9   units with out-of-date technology (i.e., Earth kiln) in lime plants will be phased out (Liu and Yin,  
10   2004; CLA, 2005). Chinese government has announced to phase out the indigenous coke  
11   production by 2010. Advanced technologies in nitric acid and sulfur acid plants are promoted in the  
12   future.

13           In 2020, total energy consumption is projected to be 134,165 PJ under the REF scenario  
14   and 122,493 PJ under the PC scenario, respectively. Compared to 2005, the energy consumption of  
15   power plants, industry and transportation in 2020 would increase sharply, as shown in Fig. 1(a).  
16   From 2005 to 2020, energy use by power plants will increase by 117% under the REF scenario and  
17   92% under the PC scenario, respectively. Jiangsu, Guangdong and Shandong are top power  
18   generation Provinces. From 2005 to 2020, energy consumption by industry will increase 82% under  
19   the REF scenario and 68% under the PC scenario, respectively. Shandong, Hebei and Shanxi are the  
20   top three industrial Provinces. Energy consumption by on-road transport in 2020 will increase 203%  
21   under the REF scenario and 190% under the PC scenario compared to that in 2005. Guangdong,  
22   Shandong and Beijing consume up to 30% of the total transport energy consumption in 2020. The

1 sectoral fuel use by each Province and each scenario is given in **Table 2**.

2         The change of the fuel structure in each sector has also been considered in this study, as  
3 shown in **Fig. 1(b)**. Although coal will still be the most important fuel for power plants and  
4 industries, the percentage of oil and gas will grow at a much faster rate. Under the REF and PC  
5 scenarios, the annual growth rate of oil is 1.28 and 1.81 times that of coal used in power plants and  
6 1.88 and 1.76 times that of coal used in industry, respectively. The percentages of the total energy  
7 consumption for coal, oil, gas and bio-fuel are 66%, 13%, 10% and 10% in 2005, 68%, 16%, 10%  
8 and 7% in the REF scenario, and 65%, 17%, 11% and 7% in the PC scenario.

## 9 **2.2 Uncontrolled Emission Factors**

10         Uncontrolled emission factors were obtained from recent references, which reported  
11 measurements from Chinese sources. The literature was thoroughly searched for published data for  
12 emission factors from domestic field measurements at power plants (Tian, 2003; Zhu et al., 2004; Yi  
13 et al., 2006; Zhao et al., 2008; Zhao et al., 2010a), industrial boilers (Wang et al., 2008; Li et al.,  
14 2007; Lei et al., 2008), and biomass and bio-fuel burning (Li et al., 2007; Li et al., 2009). A survey  
15 of the open burning of crop residues was conducted (Wang et al., 2008). Data on NMVOC emission  
16 characteristics measured in China were also collected, which included stoves burning bio-fuel and  
17 coal, road transportation, certain industrial and domestic sectors using solvent, fugitive emissions  
18 from oil exploration and distribution, and open burning of biomass (Wei et al., 2008; Wang et al.,  
19 2009). A dataset of emission factors has been documented based on these papers. All emission  
20 factors, and other assumptions used in this study can be viewed at the on-line version of the  
21 GAINS-Asia model (<http://gains.iiasa.ac.at/>), while a more detailed description is also available in  
22 the methodology document (Amann et al., 2008).

## 2.3 Air Pollution Control Legislation

Three potential air pollution control scenarios were designed for 2020, including a baseline scenario, a better implementation scenario, and a strict policy scenario. The baseline scenario (strategy-[0]) assumed that all current legislation and the implementation status of proposed legislation would be followed during 2005~2020. The better implementation scenario (strategy-[1]) considered the enhanced enforcement of current legislation and planned air pollution control measures. The strict policy scenario (strategy-[2]) assumed strict control policies and that more advanced control technologies would be implemented during 2005~2020. Tables 3~5 summarize the progress of alternative technologies on air pollution control measures under the various scenarios.

### 2.3.1 Sulfur dioxides (SO<sub>2</sub>)

**Table 3** gives the penetration of SO<sub>2</sub> control measures assumed under the three control scenarios. In strategy-[0], the most important SO<sub>2</sub> control measure is the installation of flue gas desulfurization (FGD) in power plants. The Chinese government wants to reduce national SO<sub>2</sub> emissions by 10% in 2010 on the basis of that in 2005. To achieve this goal, FGD devices are now being widely installed in coal-fired power plants. In 2005, only 15% of the power plants had FGD. By 2009, the percentage has increased to 71%. Considering that all newly-built power plants will install FGD, and some of the older plants will be retired, the percentage will continue to increase during 2010-2020. We project that in 2020, the power plants with FGD will account for 81%, 95% and 95% under strategy-[0], strategy-[1] and strategy-[2], respectively. Currently, there is no effective measure in place to control SO<sub>2</sub> emissions from industrial boilers. In strategy-[1],

1 enforcement of legislation will be strengthened so that industries can meet the current emission  
2 standards, and 50% of the coal used in industries will be low sulfur coal or briquette. In strategy-[2],  
3 30% of the industrial boilers will install FGD in order to meet emission standard. In all three  
4 strategies, Limestone Injection into Furnace (LIN) technology will be applied to all CFB Boiler. In  
5 the domestic sector, there are no control efforts being considered under baseline strategy-[0]. Under  
6 strategy-[1], we assume the application of low sulfur coal or briquette in domestic stoves will  
7 increase up to 80% in 2020. Under strategy-[2], we assume that new emission standards will be  
8 implemented for small domestic boilers; therefore, 80% of domestic boilers will use low sulfur coal  
9 or briquette in 2020.

10 Industry processes including cement plants, lime plants, coking plants and sinter plants are  
11 important SO<sub>2</sub> sources as well. For cement plants, the units with out-of-date technology such as  
12 rotary kilns and vertical kiln will be shut down. As shown in Table 4, by 2020, the percentage of  
13 advanced precalcining kilns will increase to 91% in the cement industry, which decreases the SO<sub>2</sub>  
14 emission factor (EF) by 53% compared to that in 2005. The lime plants using early kilns will  
15 decrease from 70% in 2005 to 13% in 2020, while those using modern kilns will increase from 30%  
16 in 2005 to 87% in 2020. All the indigenous coke plants will also be closed before 2020. For sinter  
17 plants, desulfurization technology is not practical under strategy-[0] and strategy-[1]. In strategy-[2]  
18 we assume that from 2015, more effort will be made to improve the control technology used in  
19 sinter plants, and that EF will be decreased by 30% in 2020 compared to that in 2005.

### 20 **2.3.2 Nitrogen Oxides (NO<sub>x</sub>)**

21 Current NO<sub>x</sub> emission control in China only involves power plants and on-road vehicles.  
22 By 2005, only about 46% of power plants had installed low NO<sub>x</sub> burners (LNB). Considering that

1 all newly-built power plants will use LNB, the application of LNB will increase to 85% in  
2 strategy-[0] by 2020. On January 27, 2010, the Ministry of Environmental Protection of the  
3 People's Republic of China (MEP) issued their "Notice of Fossil-Fired Power Plant NOx Emission  
4 Prevention and Treatment Policy" (the "Notice"). This "Notice" sets the framework for NOx  
5 reduction actions to be taken under the nation's 12<sup>th</sup> Five-Year Plan, which begins January 1, 2011.  
6 In general, the policy set forth in the "Notice" applies to all coal-fired power plants and  
7 co-generation units that are 200 MW or larger, except those in designated "Focus Areas" (areas  
8 around Beijing, Shanghai, and Guangdong) where it applies to all units regardless of size. For the  
9 units covered by the "Notice", all new, or rebuilt units that have undergone expansion should install  
10 low-NOx combustion technologies (such as LNB and Over-Fire Air systems) as a first step. For  
11 operating units, if the NOx emission levels cannot meet the emission standard, then the unit should  
12 install flue gas de-NOx technology. Major flue gas de-NOx technologies mentioned in the "Notice"  
13 includes Selective Catalytic Reduction (SCR), Selective Non-Catalytic Reduction (SNCR), and  
14 SNCR-SCR systems. Considering the implementation of this "Notice", we assume that in  
15 strategy-[1], Chinese government will promote SCR and SNCR installation in new or rebuilt power  
16 plants during 2010~2020. In 2020, the application of SCR will reach 30% under strategy-[1]. In  
17 strategy-[2], we assume stricter emission standards will be released and all new units will install  
18 SCR; therefore, the application ratio of SCR will increase to 55% in 2020.

19 Due to the lack of available control technologies, there are no controls on industrial boilers  
20 in both strategy-[0] and strategy-[1]. In strategy-[2], we assume that all newly-built industrial  
21 boilers will install LNB. The application ratio of LNB will increase to 32% in 2020.

22 For the transportation sector, both strategy-[0] and strategy-[1] will follow current mobile

1 sources control policy, while strategy-[2] assumes that starting from 2012, Euro-V will be applied to  
2 light-duty cars, Euro-III will be applied to agriculture and construction machines, and Euro-I and  
3 Euro-II will be applied to inland water ships.

4 Cement plants are also an important source of NO<sub>x</sub>. Strategy-[0] and strategy-[1] do not  
5 consider NO<sub>x</sub> emission control in cement production. Strategy-[2] assumes that SNCR will be  
6 applied to those cement plants with the precalcining technique after 2015.

### 7 **2.3.3 Particulate Matter (PM)**

8 In China, the control of particulate matter has achieved noticeable progress. A new,  
9 strengthened PM emission standard for power plants was published in 2003 ([China standards](#)  
10 [GB13223-2003](#)). Since then, all new and rebuilt units have to meet the PM emission standard with  
11 PM concentrations in flue gas less than 50 mg/m<sup>3</sup>. As a result, over 92% of pulverized coal units  
12 installed electrostatic precipitators (ESP). In addition, fabric filters have been put into commercial  
13 use for the units with a capacity of over 600 MW. In future scenarios, the ratio of units with fabric  
14 filters will increase to 15%, as shown in Table 3. In addition, all grate boilers using wet scrubbers or  
15 cyclones will be phased out or shut down. The percentage of grate boilers will decrease from 3.9%  
16 in 2005 to 1.7% in 2020.

17 Currently, industrial boilers either installed wet scrubbers or cyclones to remove PM in the  
18 flue gas. In strategy-[0], we assume that new industrial and domestic boilers will be equipped with  
19 wet scrubber. Strategy-[1] assumes both new and old boilers will be renovated with wet scrubber.  
20 Strategy-[2] suggests stricter emission standards, and new industrial and domestic boilers will be  
21 equipped with fabric filters and wet scrubbers, respectively.

#### 1    **2.3.4 Non-methane volatile organic compounds (NMVOC)**

2            Up to 2009, the existing national legislation to limit NMVOC emissions covered road  
3    vehicles (China standards GB/14622, GB/14762, GB/17691, GB/18352, GB/19756), non-road  
4    diesel engines (China standard GB/20891), wood paints (China standard GB/18581), indoor  
5    decorative paints (China standard GB/18582), adhesives used in shoemaking (China standard  
6    GB/19340), and petroleum oil distributions (China standards GB/20950~GB/20952). In this study,  
7    strategy-[0] and strategy-[1] follow these current NMVOC control legislation. Strategy-[2] assumes  
8    further controls on VOC emissions from solvent use, the chemical industry, and oil refinery plants,  
9    as shown in Table 5. The application rate of end-of-pipe treatments for related industries is 40% in  
10   2020, which is at a level similar to [EGTEI \(2008\)](#). The removal efficiencies of various measures are  
11   given in Table 5 ([European Commission, 2001](#); [EGTEI, 2008](#)). Detailed assumptions made during  
12   the control policy design period are discussed in [Wei \(2009\)](#) and [Wei et al. \(2011\)](#). With the  
13   implementation of these measures, NMVOC emissions under strategy-[2] are 10%~85% less  
14   compared to that under strategy-[0] and strategy-[1].

#### 15   **2.3.5 Ammonia (NH<sub>3</sub>)**

16            Although NH<sub>3</sub> is one important precursor of inorganic fine particles, NH<sub>3</sub> emission control  
17   has not received much attention in the current air pollutant control strategy in China. Our previous  
18   studies indicated that NH<sub>3</sub> emissions have been increasing at an annual growth rate of 3.1% from  
19   1994 to 2006 ([Dong et al., 2010](#)). The potential increase of NH<sub>3</sub> emission in the future will enhance  
20   the fine particle pollution. In strategy-[0], we project the future NH<sub>3</sub> emissions using a logistic  
21   method and historical emission data without considering any control in 2020. In strategy-[2], we

1 assume the NH<sub>3</sub> emissions will be at same level as that in 2005.

## 2 **2.4 Future emissions estimations**

3 In this study, we calculated four emission scenarios based on the above energy scenarios  
4 and emission control strategies. These emission scenarios are REF[0] (with the REF energy  
5 scenario and Strategy-[0]), PC[0] (with the PC energy scenario and Strategy-[0]), PC[1] (with the  
6 PC energy scenario and Strategy-[1]), and PC[2] (with the PC energy scenario and Strategy-[2]).

7 The predicted national SO<sub>2</sub>, NO<sub>x</sub>, and PM<sub>10</sub> emissions for different scenarios are given in  
8 **Fig. 2**. Changes in SO<sub>2</sub>, NO<sub>x</sub>, PM<sub>10</sub>, NMVOC and NH<sub>3</sub> emissions by each province for different  
9 scenarios are shown in **Fig. 3**. The changes for regional emissions for 2020 scenarios are given in  
10 **Table 6**.

### 11 **2.4.1 Future SO<sub>2</sub> emissions**

12 The SO<sub>2</sub> emissions were 28.6Tg in 2005. In 2020, SO<sub>2</sub> emissions will grow to 33.0Tg  
13 under the REF[0] scenario or decrease to 22.9Tg under the PC[2] scenario. SO<sub>2</sub> emissions decrease  
14 during the period 2005 to 2010, mainly due to FGD installations in power plants. The REF[0]  
15 scenario indicates a rapid increase of SO<sub>2</sub> emissions from industrial boilers after 2010. Industrial  
16 boilers will replace power plants to become the largest SO<sub>2</sub> emission sources. Under the PC[2]  
17 scenario, SO<sub>2</sub> emissions from industrial boilers are mainly reduced by the installation of FGD after  
18 2015.

19 Different control measures have different emission reduction potentials. In PC[2], energy  
20 savings and the improvement of energy efficiency will reduce SO<sub>2</sub> emissions by 4.1Tg. Application  
21 of low sulfur coal or briquettes in the industrial and domestic sectors will reduce SO<sub>2</sub> emissions by

1     2.9Tg. Installation of FGD in industrial boilers may reduce SO<sub>2</sub> emissions by 3.2Tg.

2             High SO<sub>2</sub> emission levels are found in east China including the North China Plain, the  
3     Yangtze River Delta (YRD), the Pearl River Delta (PRD), as well as in the Si-chuan basin.  
4     Comparing emission levels in 2020 with those in 2005, the SO<sub>2</sub> emissions will increase by 17%  
5     over east China, especially in southeast coastal provinces. Large increases are found in YRD and  
6     PRD, by 36% and 48% respectively. In PC[2], the SO<sub>2</sub> emissions will decrease by 18% over east  
7     China. However, SO<sub>2</sub> emissions in PRD will grow by 17% even in PC[2] because of the significant  
8     increase in future activities in the PRD area ([NDRC, 2008b](#)).

#### 9     **2.4.2 Future NO<sub>x</sub> Emissions**

10            Compared to those in 2005, the national NO<sub>x</sub> emissions in 2020 will increase 47% to  
11     26.7Tg in REF[0]. Even in the strict policy scenario PC[2], the NO<sub>x</sub> emissions in 2020 will be  
12     18.5Tg, 2% higher than those in 2005. Power plants, industry and transportation are the most  
13     important sources of NO<sub>x</sub> emissions, which contributed to 38%, 26%, 23%, respectively, to NO<sub>x</sub>  
14     levels in 2005. In REF[0], NO<sub>x</sub> emissions from power plants, industrial boilers and industrial  
15     process will increase by 73%, 92%, and 34% respectively, compared to those in 2005.

16            Of all the NO<sub>x</sub> control measures in PC[2], energy savings and the improvement of energy  
17     efficiency may reduce NO<sub>x</sub> emissions by 2.6Tg; application of flue gas de-nitration technology in  
18     power plants reduce NO<sub>x</sub> emissions by 1.8Tg; Implementation of stricter emission standards for  
19     industrial boilers will result in an increase in the installation of LNB and may reduce NO<sub>x</sub>  
20     emissions by 3.9Tg.

21            NO<sub>x</sub> emissions levels are highest in the east coastal regions, such as north China plain,  
22     YRD and PRD. In REF[0], the NO<sub>x</sub> emissions in east China are 50% higher than those in 2005.

1 After effective control measures are applied in PC[2], NO<sub>x</sub> emissions will remain at 2005 emission  
2 levels in national level, while increases are still found in south-east coastal regions, west and  
3 northwest China where need strengthened control efforts.

#### 4 **2.4.3 Future PM<sub>10</sub> Emissions**

5 In 2005, the PM<sub>10</sub> emissions in China were 17.1Tg. Future PM<sub>10</sub> emissions will decrease to  
6 16.0Tg in REF[0] and 11.1Tg in PC[2]. Industrial processes and the domestic sectors are the two  
7 major sources of PM<sub>10</sub> emissions; they contributed 40% and 30%, respectively, to the total  
8 emissions in 2005. Compared to those in 2005, PM<sub>10</sub> emissions from industrial processes,  
9 transportation, and domestic sources in REF[0] will decrease by 51%, 35%, and 11%, respectively,  
10 while power plants and industrial boilers will increase by 46% and 80%. In PC[2], installation of  
11 high efficiency dust collectors in industry will reduce PM<sub>10</sub> emissions by 0.01Tg and 5.0Tg from  
12 industrial boilers and industrial processes, respectively, compared to those in 2005. The reduction of  
13 PM<sub>10</sub> emissions by the installation of high efficiency dust collectors in industrial boilers are almost  
14 totally offset by the growth of coal combustion of this sector.

15 Of all the PM control measures in PC[2], energy saving and the improvement of energy  
16 efficiency may reduce PM<sub>10</sub> emissions by 1.8Tg; better implementation of emission standards may  
17 decrease the PM<sub>10</sub> emissions by 1.4Tg; Application of high efficiency dust collectors in industry  
18 may reduce PM<sub>10</sub> emissions by 1.7Tg.

19 High PM<sub>10</sub> emissions are found in east China, including north China plain, YRD and PRD.  
20 But their emissions will be well controlled in both two 2020 scenarios. The PM<sub>10</sub> emissions over  
21 east China will decrease by -10% and -38% in REF[0] and PC[2], respectively.

#### 1    **2.4.4 Future NMVOC Emissions**

2            The NMVOC emissions were 19.4 Tg in 2005. Future NMVOC emissions in China are  
3 predicted to be 26.5Tg in REF[0] and 19.9Tg in PC[2]. The control efforts applied in PC[2] will  
4 contribute to a 25% reductions of NMVOC emissions. Compared to those in 2005, the NMVOC  
5 emissions over east China will increase by 49% and 8% in REF[0] and PC[2], respectively.

#### 6    **2.4.5 Future NH<sub>3</sub> Emissions**

7            NH<sub>3</sub> emissions in China were 16.6Tg in 2005. Future NH<sub>3</sub> emissions in China are predicted  
8 to be 19.3Tg in 2020, 16% higher than those in 2005. Livestock and fertilizer applications are two  
9 major contributors, which account for over 90% of total NH<sub>3</sub> emissions. Predicted of NH<sub>3</sub>  
10 emissions indicate an increase in east coastal regions such as north China plain, YRD and PRD in  
11 2020. The NH<sub>3</sub> emissions over east China will increase by 18% over east China, in REF[0]. NH<sub>3</sub>  
12 emissions will remain the same in 2020 as those in 2005, in PC[2].

### 13    **3. Impacts of Emission Changes on Future Air Quality**

#### 14    **3.1 Air Quality Modeling System**

15            The CMAQ model, which was developed by US EPA (Byun and Ching, 1999), has been  
16 extensively evaluated by several modeling studies in Asia (Zhang et al., 2006; Streets et al., 2007;  
17 Uno et al., 2007; Fu et al, 2008; Li et al., 2008). CMAQ version 4.7 is applied in this study to  
18 simulate the air quality in China for the 2005 baseline and for the 2020 scenarios. The modeling  
19 domain covers most of China with a 36×36 km grid resolution and with nested simulations at  
20 12-km over eastern China, as shown in Fig. 4. A Lambert projection with the two true latitudes of  
21 25°N and 40°N is used. The domain origin is 34°N, 110°E. The coordinates of the bottom left corner

1 are ( $x=-2934\text{km}$ ,  $y=-1728\text{km}$ ). The vertical resolution of CMAQ includes fourteen layers from the  
2 surface to the tropopause with denser layers at lower altitudes to resolve the planetary boundary  
3 layer (PBL). The Carbon Bond Mechanism (CB05) with aqueous and aerosol extensions and the  
4 AREO5 aerosol mechanism are chosen for the gas-phase chemistry and aerosol modules,  
5 respectively. A spin-up period of seven days is used for model simulations to reduce the influence of  
6 initial conditions on model results. The boundary conditions are based on nesting from the global  
7 chemical transport model GEOS-Chem (<http://acmg.seas.harvard.edu/geos/>).

8         The fifth-generation National Center for Atmospheric Research (NCAR)/ Pennsylvania  
9 State University (PSU) Mesoscale Model (MM5), version 3.7, is applied to generate the  
10 meteorological fields needed for CMAQ simulations. In the MM5 simulations, 23 sigma levels are  
11 selected for the vertical grid structure with the model's top pressure of 100 mb at approximately 15  
12 km. The height of the first 12 levels extends up to 2 km from the surface with the lowest level at  
13 approximately 40 m. The MM5 data sources and major physics options are the same as described in  
14 our previous paper (Wang et al., 2010). The Meteorology-Chemistry Interface Processor (MCIP)  
15 version 3.4 is applied to process the meteorological data in a format required by CMAQ.

16         The CMAQ simulations of the base year emission inventory were compared and validated  
17 with satellite and surface observation data, as given by Xing et al. (2010). Generally, the model  
18 reproduces both spatial distribution and seasonal variation of tropospheric  $\text{NO}_2$  and  $\text{SO}_2$  column  
19 densities and Aerosol Optical Depth (AOD) in China that have been observed by OMI (Ozone  
20 Measurement Instrument), SCIAMACHY (Scanning Imaging Absorption Spectrometer for  
21 Atmospheric Cartography), and MODIS (Moderate Resolution Imaging Spectroradiometer).  
22 Surface concentrations of  $\text{NO}_2$ ,  $\text{SO}_2$ , and  $\text{PM}_{10}$  given by CMAQ model are also comparable with

1 those observed in Beijing, Shanghai, and Guangzhou. The results suggest that the anthropogenic  
2 emissions of SO<sub>2</sub>, NO<sub>x</sub>, and PM<sub>10</sub> used in this study are in line with both satellite and ground  
3 observations therefore are of acceptable accuracy. The performances of CMAQ simulation on ozone  
4 concentration with the same emission inventories have been validated by Li et al. (2008) for  
5 Yangtze River Delta, and Wang et al. (2010) for Beijing in July and August 2008. However, there is  
6 overestimation SO<sub>2</sub> and underestimation for PM<sub>10</sub> in some industry-intensive areas because of the  
7 inaccuracy of temporal allocations. CMAQ model also significantly underestimates PM<sub>2.5</sub>  
8 concentration in Beijing, mainly due to the underestimation of OC and EC. The absolute emission  
9 amounts may suffer from some uncertainties. So this study mainly focused on the impacts from the  
10 future emission trend which is driven by the development of future economy as well as the pace of  
11 control strategy.

12 Air quality impacts from emission changes for all species are calculated using the above  
13 MM5/CMAQ modeling system. The 2005 baseline scenario and two future scenarios (i.e.,  
14 high-emission scenario REF[0] and low-emission scenario PC[2]) has been simulated. The  
15 simulated surface concentration of SO<sub>2</sub>, NO<sub>2</sub>, 1-hour maxima O<sub>3</sub>, PM<sub>2.5</sub>, SO<sub>4</sub><sup>2-</sup>, NO<sub>3</sub><sup>-</sup> and total  
16 sulfur/nitrogen deposition in 2005 baseline scenario, as well as their changes in two future scenarios  
17 are given in Fig. 5, 6.

18 Besides, in order to explore the control benefit from each pollutant control, we have  
19 conducted 10 additional scenarios, where one pollutant is set to the two future scenario level (i.e.,  
20 REF[0] and PC[2]) and the rest are held at the 2005 level. The individual impacts of SO<sub>2</sub>, NO<sub>x</sub>,  
21 NH<sub>3</sub>, NMVOC and primary PM emission changes have been analyzed using that sensitivity  
22 analysis for three fast-developing city clusters (i.e., north China plain, YRD and PRD), as seen in

1 **Fig. 7, 8 and 9.** The air quality responses are defined as the percent change in 2020 scenarios  
2 relative to the 2005 scenario, at average regional level.

### 3 **3.2 Surface concentrations of SO<sub>2</sub> and NO<sub>2</sub>**

4 Following the continual increase of SO<sub>2</sub> and NO<sub>x</sub> emissions in REF[0], compared to that in  
5 2005, the SO<sub>2</sub> and NO<sub>2</sub> concentration will increase in most of areas (averagely by 28% and 41%  
6 domainwide), particularly higher in southeast coastal provinces, north west China which have large  
7 increase of energy use in industrial boilers and transportation. The effects of control measures can  
8 be seen from the reduction of SO<sub>2</sub> and NO<sub>2</sub> concentration in PC[2]. In PC[2], compared to that in  
9 2005, SO<sub>2</sub> concentrations will decrease by 18% domainwide, and NO<sub>2</sub> concentrations in most of  
10 areas over east China are same as those in 2005. But slight increases are found in southeast coastal  
11 provinces. More strengthen policy should be conducted focused on those area.

12 Concentrations of SO<sub>2</sub> and NO<sub>2</sub> are mainly affected by their primary emissions, as shown  
13 in **Fig. 7**, which indicates that control of the relative primary emissions is an effective way to reduce  
14 these two pollutants.

### 15 **3.3 Surface ozone concentration**

16 The ozone concentrations have strong seasonal variations. Ozone concentration is higher in  
17 April and July for most of areas over east China. Besides, higher ozone concentration also appears  
18 in October in PRD. Due to the growth of NO<sub>x</sub> and VOC emissions in REF[0], ozone concentrations  
19 in most of areas over east China increase significantly in July. Besides, ozone concentrations in  
20 south China also increase in April and October. In July, the combined effects of NO<sub>x</sub> and VOC  
21 emission growth on ozone concentrations are 8% domain-wide, compared to that in 2005.

Because of the titration reaction of NO to NO<sub>2</sub> and the VOC-limited regime (excess NO<sub>2</sub> consumes OH to generate HNO<sub>3</sub>), ozone concentrations decrease significantly in January for all areas and in April and October for north China and megacities (e.g., Guangzhou), see Fig. 6, 8. These results suggest that the effects of different ozone chemistry regimes in different seasons should be considered during NO<sub>x</sub> control policy-making. It is better to strictly control NO<sub>x</sub> emissions in summer (in summer and fall for PRD) to obtain maximal ozone reduction benefits.

### 3.4 Surface concentration of particulate matter

The future PM<sub>2.5</sub> concentrations are significantly affected by the changes of its precursor emissions (i.e., SO<sub>2</sub>, NO<sub>x</sub>, NH<sub>3</sub>, NMVOC and PM). In REF[0], the PM<sub>2.5</sub> concentration will slightly increase by 8% domainwide mainly because of the growth of SO<sub>2</sub>, NO<sub>x</sub> and NH<sub>3</sub> emissions, especially in April, July and October. Reduction of primary PM emission can compensate some increases of PM<sub>2.5</sub> concentration. Based on the stepped reductions from REF[0] to PC[2], the PM<sub>2.5</sub> concentration will decrease by 16% domainwide. Reduction of primary PM emissions plays the most important role in the decrease over east China, see Fig 8.

Because of the increase of SO<sub>2</sub> emissions in REF[0], sulfate concentrations increase by 7% domainwide. In PC[2], stricter controls of SO<sub>2</sub> emissions reduce sulfate concentration by 14% domainwide, while sulfate concentration in PRD slightly increases 9% because of the increase of SO<sub>2</sub> emissions. The growth of NO<sub>x</sub> emissions has positive impacts on the sulfate reduction because of the ozone chemistry, especially in January, April and October when VOC-limited regimes are dominating. Extra NO<sub>x</sub> emission will react with OH to obstruct its reaction with SO<sub>2</sub> to generate sulfate. Growth of NH<sub>3</sub> emissions contributes to a 3% increase in sulfate domainwide. Because NH<sub>3</sub> provides of a weak base condition to uptake more SO<sub>2</sub> and also enhance the cloud SO<sub>2</sub> oxidation

1 rate by O<sub>3</sub> (Tsimpidi et al., 2007; Makar et al., 2009).

2 In REF[0], the growth of emissions will increase the nitrate concentration by 40%  
3 domainwide, especially in April and July when atmospheric oxidization is strong and the biogenic  
4 VOC emission is large. NO<sub>x</sub> emissions are the dominate contributor, and the growth of NH<sub>3</sub> and  
5 SO<sub>2</sub> emissions also contributes to some increases of nitrate concentration caused by the  
6 thermodynamic effect (Tsimpidi et al., 2007). In PC[2], which applies stricter controls on NO<sub>x</sub>  
7 emissions, the nitrate concentration will be kept as the same level as 2005 over China, though slight  
8 increase shown in YRD and PRD.

### 9 **3.5 Total Sulfur Deposition and Nitrogen Deposition**

10 In this paper, the total sulfur deposition is defined as the wet and dry deposition of SO<sub>4</sub><sup>2-</sup>  
11 and SO<sub>2</sub> (all counted by Sulfur); the total nitrogen deposition is defined as wet and dry deposition of  
12 NO<sub>3</sub><sup>-</sup>, HNO<sub>3</sub>, NH<sub>3</sub>, N<sub>2</sub>O<sub>5</sub>, NO, NO<sub>2</sub>, peroxyacetyl nitrate (PAN), HONO, organic nitrate (NTR) (all  
13 counted by Nitrogen).

14 Because of the increase of SO<sub>2</sub> emissions in REF[0], total sulfur deposition will increase  
15 by 19% domainwide, especially higher in YRD and PRD. In PC[2], compared to that in 2005,  
16 stricter controls on SO<sub>2</sub> emission will reduce the total sulfur deposition by 15% domainwide, see  
17 **Fig. 9**.

18 Both NO<sub>x</sub> and NH<sub>3</sub> emissions have large impacts on the total nitrogen deposition, see **Fig 9**.  
19 In REF[0], the total nitrogen deposition will increase by 25% domainwide. In PC[2], which stricter  
20 controls on NO<sub>x</sub> emissions are applied and NH<sub>3</sub> emissions are kept as 2005 level, the total nitrogen  
21 deposition will only present slightly increases by 2% domainwide.

## 1    **4. Conclusions**

2            Because of the rapid growth of the economy and population, China's energy consumption  
3    by power plants and industries is predicted to double, and on-road transport is expected to be triple  
4    by 2020. Improvement of air quality is a big challenge that China is facing. It's urgent for the  
5    government to find possible solutions to reduce the primary emissions in order to protect human  
6    health and the ecosystem.

7            Based on current control legislation and proposed control (as in REF[0]), the emission of  
8    SO<sub>2</sub>, NO<sub>x</sub>, VOC and NH<sub>3</sub> will increase by 17%, 50%, 49% and 18%, respectively, in 2020, while  
9    PM will be reduced by 10% over East China, compared to those in 2005. That will lead to a  
10   significant impact on air quality. CMAQ simulations indicate that the concentration of SO<sub>2</sub> and NO<sub>2</sub>  
11   will increase by 28% and 41% domainwide in annual mean level. The daily 1-h maximum  
12   concentration of ozone in summer will increase by 8%. The concentration of sulfate and nitrate will  
13   increase by 7% and 40%. In addition, total sulfur depositions are predicted to increase by 19% and  
14   25%, respectively.

15           A detailed step-by-step control implementation plan has been designed in this study. If a  
16   more sustainable energy development strategy is adopted to improve the energy efficiency, the  
17   emissions of SO<sub>2</sub>, NO<sub>x</sub> and PM<sub>10</sub> will be reduced by 4.1 Tg, 2.6 Tg, and 1.8 Tg, respectively. If  
18   current control policies is well implemented and the pollution sources can meet the emission  
19   standard, SO<sub>2</sub>, NO<sub>x</sub> and PM<sub>10</sub> emissions will be reduced by 2.9 Tg, 1.8 Tg, and 1.4 Tg, respectively.  
20   Furthermore, if stricter policy standards are adopted to promote the applications of advanced control  
21   technologies, the SO<sub>2</sub>, NO<sub>x</sub> and PM<sub>10</sub> emissions will be reduced by 3.2 Tg, 3.9 Tg, and 1.7 Tg,  
22   respectively.

1 In the strict emission control scenario (PC[2]), the SO<sub>2</sub> and PM<sub>10</sub> emissions will decrease  
2 by 18% and 38%, compared to those in 2005, while the NO<sub>x</sub> and VOC emissions will increase by  
3 3% and 8%, respectively. NH<sub>3</sub> emissions are kept at same level as those in 2005. After all the  
4 substantial emission controls, the future air quality is able to maintain as 2005 level, over East  
5 China, while the southeast coastal provinces and inter-Mongolia and Shanxi, need more  
6 strengthened control actions on the SO<sub>2</sub> and NO<sub>x</sub> emissions in industry boiler and transportation.

7 While NH<sub>3</sub> has not been considered in the current air pollutant control strategy in China, its  
8 impact on PM<sub>2.5</sub> concentrations is important. In addition, NH<sub>3</sub> emissions have significant impacts  
9 on total nitrogen deposition in the future. NH<sub>3</sub> emission controls should be considered as well.

10 There are several limitations in this study. First, the absolute values in this study suffer the  
11 uncertainties in the emissions, e.g., previous studies indicate that the uncertainties (i.e., 95%  
12 confidence intervals around the central estimates) in our base year emissions are -14%~12% (SO<sub>2</sub>),  
13 -10%~36% (NO<sub>x</sub>), -44%~109% (NMVOC), and -12%~42% (PM<sub>10</sub>), respectively (Wei et al., 2008;  
14 Zhao et al., 2010b). These uncertainties pose more difficulties for the accurate forecast of future air  
15 quality in China. Secondly, the model biases may affect the results of future projections on air  
16 quality. For example, the limitation of SOA formation mechanism used in the model may  
17 underestimate the impact from the future growth of VOC emissions, which is considered as another  
18 important species to fine particles (Xing et al., 2010). However, this study aims to project the  
19 relative changes of future emissions according to the development of future economy as well as the  
20 pace of control strategy and the potential impacts of future emission on regional air quality in China.  
21 Therefore the results can provide important reference for the air pollution control policy-making.

This study is financially supported by Natural Science Foundation of China (20921140095 and 20921140409), National High Technology Research and Development Program of China (2006AA06A309), and Toyota Motor Corporation The authors thank to Ke-Jun Jiang and Yi-Xiang Deng from Energy Research Institute of China for their help on energy projection; Carey Jang from U.S. EPA and Yun Zhu from South China University of Technology for their help on air quality modeling; Jerry Davis from U.S. EPA/NCSU for his help in editing.

Table 1. Key parameters used in the development of energy scenarios

Scenario		2005	Reference Scenario [REF]	Policy Scenerio [PC]
Power plants (PP)	Electricity production (billion kW·h)	2,055	5,226 (annual growth rate: 6.4%)	4,759 (annual growth rate: 5.8%)
	Thermal efficiency	32.0%	37.5%	38.5%
	Percentage of coal power	95.2%	95.3%	93.6%
Industry (IND)	Energy consumption (PJ)	30,678	70,528 (annual growth rate: 4.1%)	66,155 (annual growth rate: 3.5%)
	Energy structure (ratio of coal, oil, gas and electricity)	59%, 10%, 11% and 20%	57%, 9%, 14%, and 20%	54%, 9%, 16%, and 21%
Domestic (DOM)	Energy consumption (PJ)	16,333	21,786 (annual growth rate: 1.9%)	20,438 (annual growth rate: 1.5%)
	Energy structure (ratio of coal, gas, biomass, electricity and heat)	25%, 9%, 47%, 14% and 4%	16%, 11%, 41%, 25% and 7%	14%, 12%, 41%, 26% and 7%
Transport (TRA)	Vehicle population of truck, car, and motor cycle (million)	9.55, 21.33 and 75.8	21.29, 136.7 and 98.0	
	Fuel economy of car, truck, motorcycle, and agriculture transport machine		Increase by 30%, 25%, 30% and 15%	Increase by 40%, 36%, 36% and 23%

Table 3. Penetration of selected air pollution control measures assumed under three control scenarios

Sector	Sub-sector	Control technology	2005	[0]-Baseline	2020 scenario [1]-Better implementation	[2]-Strict policy
Power plants	Old units	FGD(SO <sub>2</sub> )	15%	45%	85%	85%
		LNB(NO <sub>x</sub> )	46%	46%	100%	100%
	New units	FGD(SO <sub>2</sub> )		100%	100%	100%
		SCR(NO <sub>x</sub> )			45%	85%
		LNB(NO <sub>x</sub> )		100%	100%	100%
	Grate boiler	CYC(PM)	40%	40%	100%	
		WET(PM)	60%	60%		
		ESP(PM)				85%
		FF(PM)				15%
	Pulverized coal boiler	WET(PM)	8%			
ESP(PM)		92%	85%	85%	85%	
FF(PM)			15%	15%	15%	
Industrial combustion	Grate boiler	FGD(SO <sub>2</sub> )			50%	30%
		LSC(SO <sub>2</sub> )				50%
		LNB(NO <sub>x</sub> )				32%
		CYC(PM)	23%	6%		
		WET(PM)	73%	93%	100%	43%
		FF(PM)				57%
	Circulating Fluidized-Bed (CFB) boiler	LIN(SO <sub>2</sub> )	100%	100%	100%	100%
		WET(PM)	100%	100%	100%	24%
		FF(PM)				76%
	Domestic	Stove	LSC(SO <sub>2</sub> )			80%
Boiler		LSC(SO <sub>2</sub> )				80%
		CYC(PM)	23%	10%		
		WET(PM)	63%	83%	100%	84%
FF(PM)				16%		
Transport	Car-gasoline	Uncontrolled	39%			
		EURO-I	38%			
		EURO-II	23%	6%	6%	6%
		EURO-III		17%	17%	17%
		EURO-IV		78%	78%	13%
		EURO-V				65%
	Car-diesel	Uncontrolled	2%			
		EURO-I	59%			
		EURO-II	39%	3%	3%	3%
		EURO-III		10%	10%	10%
		EURO-IV		87%	87%	11%
		EURO-V				76%
	Trucks-diesel	Uncontrolled	33%			
	EURO-I	40%				

	EURO-II	27%	4%	4%	4%
	EURO-III		12%	12%	12%
	EURO-IV		11%	11%	11%
	EURO-V		73%	73%	73%
Agriculture, construction machine	Uncontrolled	100%	100%	100%	
	EURO-I				13%
	EURO-II				12%
	EURO-III				41%
Inland water	Uncontrolled	100%	100%	100%	
	EURO-I				13%
	EURO-II				32%

---

Notes: FGD- Flue Gas Desulfurization; LSC- low-sulfur coal; LIN- Limestone Injection into Furnace; SCR- Selective Catalytic Reduction; LNB- Low NOx burner; CYC- mechanical dust collector; WET- wet dust collector; ESP- Electrostatic precipitation; FF- Fabric Filter

Table 4. Technology changes of selected industrial processes

Sector	Technology	2005	2020
Power plants	Grate boiler	3.9%	1.7%
	Pulverized coal boiler	96.1%	98.3%
Industry boiler	Grate boiler	90%	85%
	Circulating Fluidized-Bed (CFB) boiler	10%	15%
Cement plant	Rotary kiln	4%	1%
	Vertical kiln	49%	7%
	Precalcining kiln	47%	91%
Lime plant	Earth kiln	70%	13%
	Modern kiln	30%	87%
Coke plant	Indigenous coke	8%	0%
	Machine coke	92%	100%

Table 5. Penetration of selected NMVOC control technologies in industry and solvents

Sector	Sub-sector	Technology	Removal efficiency	VOC reduction in strategy-[2] compared to that in [0]/[1]
Industrial process	Chemical industry	Reduction of vent losses	70%	-21%
	Crude oil refineries	Inspection and maintenance; Install vapor recovery units	95%	-10%
	Coking plants			-70%
	Chemical pharmaceutical factory	End-of-pipe control technology	90%	-85%
	Vegetable oil Extraction			-29%
Solvent use	Ink printing	Solvent management and substitution	50%~100%	-64%
	Paint use			-38%
	Glues and adhesives	End-of-pipe technology applied on new plants	90%	-30%
Fuel transport, storage and distribution	/	Install vapor recovery units	95%	-50%

Table 6. Changes of emission intensity in 2020 among regions and sectors (compared to 2005 level, %)
