Thanks for clarifying the “linear regression” approach that has been/ has not been used in your study.

Now, when you addressed my attention to Fig. 5, I'd like to make one more comment. Although there are only 4 points in this plot without error bars, it is quite possible, I guess, that they may show not a linear trend, but an exponential growth of Y when X=PM10 increases from a threshold level of ~ 24 to about 60 mg/m³. Then the rate of increase is slowing down and Y approaches some level of saturation at high X. Of course, this is just a speculation, but for prediction purposes “my scenario” is quali-

C11941

tatively different compared to a continuous approximately linear dependence Y on X. Does it make any sense to you?
