Received and published: 3 July 2011

We would like to thank R.J. Van der Ent for his interest and his constructive comments. We agree with his comments and propose to reformulate Section 4.1 as follow.

Minor comments:

1. Section 4.1 Origin of water in global land precipitation. “Thereby, in agreement with previous studies (e.g. Wild et al., 2008), we find that at least 35 % (260 mm/year) of global land precipitation must come from oceanic evaporation (Fig. 8b, black curve), meaning that quantitatively, a maximum of 65% of the global land precipitation can come from land evaporation. However, Van der Ent et al. (2010) show that only about 57% of the water evaporated on land falls back on land. This means that in reality, only

C5893

40% of the global land precipitation comes from land evaporation. Nevertheless, our results show that in the 11 years running mean time series, the global land precipitation trend (-0.92 mm/decade) and variability are more highly correlated with the trend (-0.77 mm/decade) and variability ($r^2=0.81$) of the global land evaporation, as opposed to global oceanic evaporation (trend=-0.15 mm/decade, $r^2 = 0.36$). The next sections investigate the sensitivity of the global land and oceanic evaporation to changing external forcings since 1870. “

2. We agree with the comment, I will change the legend
