## Cover Sheet for Supporting Information (SI)

# Simulation of aromatic SOA formation using the lumping model integrated with explicit gas-phase kinetic mechanisms and aerosol-phase reactions 

Authors: Yunseok Im, Myoseon Jang* and Ross Beardsley<br>Department of Environmental Engineering Sciences, University of Florida P.O. Box 116450, Gainesville, FL 32611, USA<br>Number of Figures: 9<br>Number of Tables: 5

## Section S1. Chamber Studies

Chamber operation The University of Florida Atmospheric PHotochemical Outdoor Reactor (UF-APHOR) dual chambers are located on the roof of Black Hall (latitude/longitude: $29.64185^{\circ} /-82.347883^{\circ}$ ) at the University of Florida, Gainesville, Florida. The air volume of the two half-cylinder shaped dual chambers is $104 \mathrm{~m}^{3}\left(52 \mathrm{~m}^{3}+52 \mathrm{~m}^{3}\right)$. The walls of the chamber are made of 5mil FEP Teflon film and the surface to volume ratio of each chamber is $0.20 \mathrm{~m}^{-1}$. For the sunlight characterization, sunlight spectrum and intensity were measured both inside and outside of the chamber using the spectroradiometer (Apogee, PS-300) and the ultraviolet radiometer (The Eppley Laboratory, model TUVR, wavelength 290 to 385 nm ), respectively. Then the sunlight source was characterized using the chamber experiment of acetaldehyde photolysis. Also, the wall loss rate constant of ozone was measured through a separate experiment.

Figure S1. The University of Florida Atmospheric Photochemical Outdoor Reactor (UF-APHOR) dual chambers and experimental setup.

Experimental instruments. The gaseous and aerosol samples were directly carried to laboratory instruments from the chamber through sampling conduit that holds various sampling lines. The concentrations of AVOC and $\mathrm{CCl}_{4}$ were monitored using a gas chromatography-flame ionization detector (HP-5890 GC-FID) with a DB5 fused silica capillary column ( $15 \mathrm{~m}, 0.53 \mathrm{~mm}$ i.d., $1.5 \mu \mathrm{~m}$ thickness, J \& W Scientific INC., Cat\# 1255012). The GC oven temperature was fixed at $110^{\circ} \mathrm{C}$ and the carrier gas (nitrogen) flow rate was $10.0 \mathrm{~mL} \mathrm{~min}^{-1}$. The concentrations of $\mathrm{O}_{3}$ and $\mathrm{SO}_{2}$ were monitored with a photometric ozone analyzer (Teledyne, model 400E) and a fluorescence TRS analyzer (Teledyne model 102E), respectively. Temperature and relative humidity (RH) were measured using Temp/RH sensors (Campbellscientific, CS215-L) for both chambers. The solar UV radiation was monitored by an ultraviolet radiometer (The Eppley Laboratory, model TUVR, wavelength 290 to 385 nm ) installed in the East chamber. All meteorological data were recorded over the course of the experiment using the data logger system (Campbellscientific, CR800). The particle volume concentration was monitored with a scanning mobility particle sizer (SMPS, TSI, Model 3080) integrated with a condensation nuclei counter (TSI, Model 3025A and Model 3022). The SMPS sampling and sheath flow rates were 0.3 and $2 \mathrm{~L} \mathrm{~min}^{-1}$, respectively. The particle wall loss rate for each particle size bin was measured as first order in a separate experiment and applied to the other chamber experiments (Keywood et al., 2004). The organic carbon (OC) content in aerosols was monitored using a semi-continuous OC/EC carbon aerosol analyzer (Sunset Laboratory, Model 4) with 40 minutes cycle ( 26 min sampling and 14 min analyzing). Inorganic ions in aerosols were measured using a PILS-IC (Particle into Liquid Sampler (Applikon, ADI 2081) - Ion chromatography (Metrohm, 761Compact IC)) every 30 min . An aqueous solution comprising 9.67 mM of $\mathrm{NaCO}_{3}$ and 2.47 mM of $\mathrm{NaHCO}_{3}$ was used for anion eluent. A $2.0 \mathrm{mM} \mathrm{HNO}_{3}$ aqueous solution was used as a cation eluent. A 4.6 $\mu \mathrm{M} \mathrm{LiBr}$ solution was used as an internal standard for PILS-IC. Particle acidity was measured using a colorimetric integrated with a reflectance UV-visible spectrometer (C-RUV) which is developed by Jang et al. (2008).

Two days before the experiment, the chamber was flushed with the clean air using a clean air generator (GC Series, IQAir). Before sunrise, the gaseous compounds and aerosols in the background air inside the chamber were measured. The aromatic volatile organic compound (AVOC) (toluene or 135-TMB) was injected into the chamber using a glass chemical injector
under clean air stream. About 1 ppm of carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ was also added to the chamber as a non-reactive tracer to account for dilution. Gaseous nitrous acid (HONO) that was synthesized through the reaction of 25 ml of $0.1 \mathrm{M} \mathrm{NaNO}_{2}$ and 25 ml of $10 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ in a conical flask was introduced into the chamber by passing the clean air stream through the flask. The initial concentration of $\mathrm{NO}_{\mathrm{x}}$ including HONO , was measured using a chemiluminescence $\mathrm{NO} / \mathrm{NO}_{2}$ analyzer (Teledyne, model 200E) with molybdenum converter which can convert $100 \%$ of HONO to NO at $350^{\circ} \mathrm{C}$. The HONO concentration was measured by a difference in $\mathrm{NO}_{\mathrm{x}}$ concentrations between with and without the denuder $\left(1 \% \mathrm{Na}_{2} \mathrm{CO}_{3}+1 \%\right.$ glycerol coated) that adsorbs HONO (Febo and Perrino, 1991). Sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ was injected into the chamber from a tank of 500 ppm SO 2 . All gas (AVOC, $\mathrm{CCl}_{4}, \mathrm{NO}_{\mathrm{x}}, \mathrm{O}_{3}$ and $\mathrm{SO}_{2}$ ) and particle (OC/EC, particle distribution, aerosol inorganic ions and aerosol acidity) data were alternatively measured between the east and west chambers by switching sampling valves over the course of experiment.

Figure S2. Simulation of gas-phase oxidation of toluene and 135-TMB.

Time profiles of measured (symbols) and simulated (solid lines) concentrations of AVOCs, $\mathrm{NO}_{\mathrm{x}}$, and $\mathrm{O}_{3}$ for toluene and 135-TMB under low and high $\mathrm{NO}_{\mathrm{x}}$ conditions (A: Exp 01/06/12E, B: Exp 02/09/12E, C: $\operatorname{Exp} 05 / 20 / 12 \mathrm{E}, \mathrm{D}: \operatorname{Exp} 05 / 18 / 12 \mathrm{E}$ ). For the toluene experiments (Figs. S2A, S 2 B ), toluene decay, $\mathrm{NO} / \mathrm{NO}_{2}$ conversion and $\mathrm{O}_{3}$ production are reasonably predicted, and for the 135-TMB experiments (Figs. S2C, S2D), 135-TMB decay and $\mathrm{O}_{3}$ formation are reasonably estimated but $\mathrm{NO}_{2}+\mathrm{HONO}$ concentrations (instrumentally, $\mathrm{NO}_{2}$ measurement includes HONO) appear to decrease faster than measured concentrations after 09:00 EST. This may be partially explained by an instrumental artifact in that organic nitrate compounds are detected as $\mathrm{NO}_{2}$ in the chemiluminescence $\mathrm{NO}_{\mathrm{x}}$ analyzer.

## Section S2. Description of the concentrations of organic compounds in aqueous phase

To describe the concentrations of organic compounds in the inorganic aqueous phase, the estimation of the gas-particle partition coefficient ( $K_{i n, i}$ ) of an organic compound between the gas and inorganic aerosol phases is necessary. $K_{\text {in, } i}$ is expressed as (Pankow, 1994),

$$
\begin{equation*}
K_{i n, i}=\frac{7.501 R T}{10^{9} M W_{\text {in }} \gamma_{i n, i} p_{l, i}^{o}} \tag{S1}
\end{equation*}
$$

where $R$ is the gas constant $\left(8.314 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}\right), T$ is the temperature $(\mathrm{K})$, and $M W_{i n}$ is the average molecular weight $\left(\mathrm{g} \mathrm{mol}^{-1}\right)$ of inorganic aerosols. $p^{o}{ }_{l, i}$ is the sub-cooled liquid vapor pressure $(\mathrm{mmHg})$ of compound, $i . \gamma_{i n, i}$ is the activity coefficients of the organic compound, $i$ in the inorganic phases. The concentrations of organic compounds in aqueous solution are affected by inorganic salt concentrations. Generally, less organic compounds are soluble in aqueous solutions with higher salt concentrations. To incorporate the solubility of organic compounds in atmospheric aerosols with different RH in the model, which usually contain inorganic salts, the activity coefficient of organic compounds should be calculated in salt water. However, there are currently no available thermodynamic models that can calculate the activity coefficient of organic compounds in salt water. Therefore, in this study, the activity coefficient of organic compounds in pure water is calculated first using Hansen's cohesive energies and solubility parameter method (Barton, 1991) and then corrected to the one in salted aqueous aerosol at $70 \%$ RH using the empirically obtained relationship of activity coefficients of organic compounds in pure water and in NaCl aqueous aerosol at $70 \% \mathrm{RH}$ (literature solubility data of NaCl were used because of the lack of literature data for ammonia-sulfate aerosol) (Fig. S3 and Table S1). Each inorganic salt requires a certain amount of water to liquefy at the deliquesce relative humidity (DRH, solid to liquid). Similarly, when humidity drops from very high to DRH, salt will retain a certain amount of water until the efflorescence relative humidity (ERH) is reached. The majority of the water solubilities of organic compounds are available for low concentrations that correspond to high humidities. Thus, the activity coefficients of organic compounds in low concentration in water, which is related to $70 \% \mathrm{RH}$, are used to estimate the solubility of organic compounds in salt aerosols.

Figure S3. Regression of the activity coefficient ratio of organic compounds in pure water to NaCl salted water at $70 \% \mathrm{RH}$.

Table S1. Experimental activity coefficients of organic compounds in pure water and $30 \% \mathrm{NaCl}$ salted water.

## Section S3. Derivation of analytical solution of $\boldsymbol{\Delta O M _ { A R }}$

For convenience, all equations in the supporting information are numbered independently from the manuscript, although some equations are shown in the manuscript.

The partitioning coefficients of lumping species, $i$ between gas $(g)$ and two condensed phases (organic phase, or and inorganic phase, in) can be expressed using $K_{o r, i}\left(\mathrm{~m}^{3} \mu \mathrm{~g}^{-1}, g \leftrightarrow o r\right)$ and $K_{i n, i}\left(\mathrm{~m}^{3} \mu \mathrm{~g}^{-1}, g \leftrightarrow i n\right)$.

$$
\begin{align*}
& K_{o r, i}=\frac{C_{o r, i}}{C_{g, i} O M_{T}}  \tag{S2}\\
& K_{i n, i}=\frac{C_{i n, i}}{C_{g, i} M_{i n}} \tag{S3}
\end{align*}
$$

where $C_{g, i}, C_{\text {or, } i}$ and $C_{i n, i}$ are concentrations ( $\mu \mathrm{g} \mathrm{m}^{-3}$ of air) of lumping species, $i$ in the gas, organic and inorganic aerosol phases, respectively. $O M_{T}$ is the total organic aerosol mass concentration ( $\mu \mathrm{g} \mathrm{m}^{-3}$ ) and $M_{i n}$ is the inorganic aerosol mass concentration ( $\mu \mathrm{g} \mathrm{m}^{-3}$ ).

The concentrations of each lumping species in the gas, organic aerosol, and inorganic aerosol-phases are derived from the Eqs. (S2) and (S3).

$$
\begin{gather*}
C_{g, i}=\frac{1}{1+K_{o r, i} O M_{T}+K_{i n, i} M_{i n}} C_{T, i}  \tag{S4}\\
C_{o r, i}=\frac{K_{o r} O M_{T}}{1+K_{o r, i} O M_{T}+K_{i n, i} M_{i n}} C_{T, i}  \tag{S5}\\
C_{i n, i}=\frac{K_{i n} M_{i n}}{1+K_{o r, i} O M_{T}+K_{i n, i} M_{i n}} C_{T, i} \tag{S6}
\end{gather*}
$$

where $C_{T, i}\left(\mu \mathrm{~g} \mathrm{~m}^{-3}, C_{T, i}=C_{g, i}+C_{o r, i}+C_{i n, i}\right)$ is the total concentration of lumping species, $i$.

In the UNIPAR model, organic matter $\left(\Delta O M_{A R}\right)$ formed by aerosol phase reactions are described by two processes, the oligomerization in the organic phase and acid-catalyzed reaction
in the inorganic phase. The reactions in both the phases are derived based on a second order kinetic self-dimerization reaction.

$$
\begin{array}{lll}
\frac{d C_{o r, i}^{\prime}}{d t}=-k_{o, i} C_{o r, i}^{\prime}{ }^{2} & \text { (In the organic phase) } & \text { (S7) [Eq. (7) in the manuscript] } \\
\frac{d C_{i n, i}^{\prime}}{d t}=-k_{A C, i} C_{i n, i}^{\prime 2} & \text { (In the inorganic phase) } & \text { (S8) [Eq. (8) in the manuscript] }
\end{array}
$$

where $C_{o r, i}^{\prime}$ and $C_{i n, i}^{\prime}$ are the aerosol-based concentration of lumping species, $i\left(\mathrm{~mol} \mathrm{~L}^{-1}\right)$. $k_{o, i}$ is the $2^{\text {nd }}$ order reaction rate constant $\left(\mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}\right)$ for oligomerization of lumping species, $i$ in the organic phase. $k_{A C, i}$ is the $2^{\text {nd }}$ order reaction rate constant $\left(\mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}\right)$ for acid-catalyzed reaction of lumping species, $i$ in the inorganic phase. Aerosol based concentration $C_{x, i}^{\prime}\left(\mathrm{mol} \mathrm{L}^{-1}\right)$ and air-based concentration $C_{x, i}\left(\mu \mathrm{~g} \mathrm{~m}^{-3}\right)(x=o r$, in $)$ can be converted by unit conversion factor $f_{o r, i}$ and $f_{i n, i}$, defined as follow.

$$
\begin{align*}
& f_{o r, i}=\frac{C_{o r, i}}{C^{\prime}{ }_{o r, i}}=\left(\frac{M W_{i} \cdot O M_{T}}{\rho_{o r} 10^{3}}\right)  \tag{S9}\\
& f_{i n, i}=\frac{C_{i n, i}}{C^{\prime}{ }_{i n, i}}=\left(\frac{M W_{i} \cdot M_{i n}}{\rho_{i n} 10^{3}}\right) \tag{S10}
\end{align*}
$$

where $M W_{i}$ is the molecular weight of lumping species $i . \rho_{\text {or }}$ and $\rho_{i n}$ are the densities of the organic phase and inorganic phase.

The amount of OM formed by the aerosol phase reactions $\left(\Delta O M_{A R}\right)$ is same as the amount of consumed total concentrations ( $C_{T, i}$ ) of lumping species based on a mass balance. Therefore, the $\Delta O M_{A R}$ can be expressed as

$$
\Delta O M_{A R}=-\sum_{i} \Delta C_{T, i}=-\sum_{i} \int d C_{T, i} \quad \text { (S11) (Eq. (10) in the manuscript) }
$$

To solve Eq. (S11), all of partitioning and aerosol phase reactions in the multi-phase system are kinetically described. (Fig. (S4))

Figure S4. Kinetic scheme for SOA formation in the UNIPAR model.
Kinetic expressions of lumping components are shown in following equations.

$$
\begin{align*}
& \frac{d C_{g, i}}{d t}=k_{11} C_{o r, i}-k_{12} C_{g, i}+k_{21} C_{i n, i}-k_{22} C_{g, i}  \tag{S12}\\
& \frac{d C_{o r, i}}{d t}=-k_{11} C_{o r, i}+k_{12} C_{g, i}-k_{31} C_{o r, i}+k_{32} C_{i n, i}-k_{o, i} C_{o r, i}^{2} f_{o r, i}  \tag{S13}\\
& \frac{d C_{i n, i}}{d t}=-k_{21} C_{i n, i}+k_{22} C_{g, i}+k_{31} C_{o r, i}-k_{32} C_{i n, i}-k_{A C, i} C_{i n, i}^{2} f_{i n, i} \tag{S14}
\end{align*}
$$

where $k_{n m}$ are first order reaction rate constants $\left(n, m=1-3, \mathrm{~s}^{-1}\right)$, in which each pair of them represents equilibrium among $C_{g, i}, C_{o r, i}$ and $C_{i n, i}$.

From Eqs. (S12)-(S14), $\frac{d C_{T, i}}{d t}$ can be expressed as follow,

$$
\begin{equation*}
\frac{d C_{T, i}}{d t}=\frac{d C_{g, i}}{d t}+\frac{d C_{o r, i}}{d t}+\frac{d C_{i n, i}}{d t}=-k_{o, i} C_{o r, i}^{2} f_{o r, i}-k_{A C, i} C_{i n, i}^{2} f_{i n, i} \tag{S15}
\end{equation*}
$$

Using the Eqs. (S5), (S6), (S9), and (S10), Eq. (S15) can be rearranged with respect to $C_{T, i}$.

$$
\begin{equation*}
\frac{d C_{T, i}}{d t}=-\left(k_{o, i} \frac{o M_{T} 10^{3} \rho_{o r} K_{o r, i}^{2}}{M W_{i}\left(1+K_{o r, i} O M_{T}+K_{i n, i} M_{i n}\right)^{2}}+k_{A C, i} \frac{M_{\text {in }} 10^{3} \rho_{i n} K_{i n, i}^{2}}{M W_{i}\left(1+K_{o r, i} O M_{T}+K_{i n, i} M_{i n}\right)^{2}}\right) C_{T, i}^{2} \tag{S16}
\end{equation*}
$$

Assuming the parameters in Eq. (S16), such as $O M_{T}, M_{i n}$, and $k_{A C, i}$ are constants during computational time interval ( $\Delta t=3 \mathrm{~min}$ ), $\mathrm{Eq}(\mathrm{S} 16)$ can be integrated as a general second order differential equation.

$$
\begin{equation*}
\Delta O M_{A R}=-\sum_{i} \int d C_{T, i}=-\sum_{i} \int_{0}^{\Delta t}\left(k_{o, i} \beta_{1, i}+k_{A C, i} \beta_{2, i}\right) C_{T, i}^{2} \mathrm{dt} \tag{S17}
\end{equation*}
$$

where $\beta_{1, i}=\frac{O M_{T} 10^{3} \rho_{o r} K_{o r, i}^{2}}{M W_{i}\left(1+K_{o r, i} O M_{T}+K_{i n, i} M_{i n}\right)^{2}}$

$$
\beta_{2, i}=\frac{M_{\text {in }} 10^{3} \rho_{\text {in }} K_{\text {in,i }}^{2}}{M W_{i}\left(1+K_{\text {or }, i} O M_{T}+K_{\text {in }, i} M_{\text {in }}\right)^{2}}
$$

Then the analytical solution of $\Delta O M_{A R}$ can be obtained.

$$
\begin{equation*}
\Delta O M_{A R}=-\Delta \mathrm{C}_{T, i}=\sum_{i} \frac{\left(k_{o, i} \beta_{1, i}+k_{A C, i} \beta_{2, i}\right) c_{T, i}^{2} \Delta t}{1+\left(k_{o, i} \beta_{1, i}+k_{A C, i} \beta_{2, i}\right) c_{T, i} \Delta t} \tag{S18}
\end{equation*}
$$

## Section S4. Description of the formation of organosulfate.

Parameter ( $\boldsymbol{N}_{O S}$ ) to count functional groups involved in OS formation. $N_{O S}$ accounts for aldehyde, epoxide, and alcohol in this study. These functional groups are related to the reactivity of lumping groups. Fast $[\mathrm{F}]$ and medium $[\mathrm{M}]$ reactivity groups have two and one aldehyde or epoxide functional groups, respectively. Each aldehyde can react with two sulfate ion positions (Liggio and Li, 2006). Therefore, fast reactivity groups have a weighting factor of 4, and medium reactivity groups have a weighting factor of 2 in the model. For the multi-alcohol [MA] groups, the least volatile group ( $i=1$ ) has a weighting factor of 4 , and the second and third less volatile groups ( $i=2$ and 3 ) use a weighting factor of 3 .

$$
\begin{equation*}
N_{O S}=\sum_{i=1}^{30} w_{i} \cdot \Delta O M_{A C, i}^{\prime} \tag{S19}
\end{equation*}
$$

$w_{i}$ is the weighting factor that numerically estimate the capability of each lumping group for the formation of OS. $\triangle O M^{\prime}{ }_{A C, i}$ is the molar concentration $(\mu \mathrm{mol} \mathrm{m} ~ \mathrm{~m}$ ) of $O M$ formed through acidcatalyzed reaction of each lumping group, $i$ in the inorganic phase during $\Delta t$.

Table S2. Weighting factor $\left(w_{i}\right)$ of each lumping group for the calculation of the number of OSformable functional groups, $N_{O S}$

Empirical parameter ( $f_{o s}$ ) to estimate OS formation. The change of aerosol acidity due to the formation of OS can be experimentally estimated by comparison of the proton concentration ( $\left[\mathrm{H}^{+}\right]$) from the PILS-IC measurement and the C-RUV measurement. The PILSIC measurement provides ion concentrations, such as ammonium and sulfate, and the [ $\mathrm{H}^{+}$] of aerosol can be calculated using an aerosol thermodynamic model (E-AIM II). For ammonia-rich aerosols $\left(\left[\mathrm{NH}_{4}^{+}\right] /[\right.$total sulfate $\left.] \geq 1\right)$, the $\left[H^{+}\right]$was estimated from the empirical data by Li and

Jang (2012). The C-RUV method directly measures the $\left[\mathrm{H}^{+}\right]$of aerosols by collecting the aerosol on a metanil yellow dyed filter, which changes color from yellow to pink in acidic conditions, and subsequently measuring the filter color change using reflectance UV-Visible spectrometry. By comparing the proton concentrations from PILS-IC measurement with C-RUV measurement, acidity change by OS formation can be estimated. For this study, the chamber experiment $(06 / 20 / 12 \mathrm{E})$ was conducted for the toluene and $\mathrm{NO}_{\mathrm{x}}$ system with sulfuric acid seeds. The resulting proton concentrations are shown in Fig. S3. Then, the OS formation parameter fos (0.017) in Eq. (S14) was obtained by fitting the modeled proton concentration to the C-RUV measured concentration.

$$
\text { OS converstion factor }=\frac{\left[\mathrm{SO}_{4}^{2-}\right]_{\text {old }}-\left[\mathrm{SO}_{4}^{2-}\right]_{\text {new }}}{\left[\mathrm{SO}_{4}^{2-}\right]_{\text {old }}}=\frac{\Delta O S}{\left[\mathrm{SO}_{4}^{2-}\right]_{\text {old }}}=1-\frac{1}{1+f_{o S} \cdot \frac{N_{O S}}{\left[\mathrm{SO}_{4}^{2-}\right]_{\text {free }}}}
$$

(S20) (Eq. (12) in the manuscript)

Figure S5. Time profile of aerosol proton concentration for the toluene experiment with sulfuric acid seeds.

## Section S5. Lumping of gas phase oxidation products

Vapor pressures of model-predicted photooxidation products are estimated as a function of boiling point and entropy of vaporization (detailed method is described in elsewhere (Cao and Jang, 2010;Jang and Kamens, 2001)). The reactivity for aerosol phase reaction is determined based on products' functional groups: the product containing more than two aldehyde or epoxide functional groups is categorized into group F , the product containing an aldehyde or epoxide functional groups is for group M , the product containing ketone functional groups is for group S , and the product without those functional groups is for group P. Among the group P, the products with more than three of alcohol functional groups are designated to group MA, which is later used for the estimation of organosulfates with other reactive products (see section "organosulfate formation").

## Section S6. $\mathbf{N O}_{\mathrm{x}}$ dependency of the stoichiometric coefficient matrix

To consider the effect of $\mathrm{NO}_{\mathrm{x}}$ on SOA formation, mass based product stoichiometric coefficients $\left(\alpha_{i, j}\right)$ are evaluated in various $\mathrm{NO}_{\mathrm{x}}$ conditions using gas-phase kinetic model (MCM V3.2). Toluene or 135TMB are simulated in several VOC/NO $\mathrm{NO}_{\mathrm{x}}$ conditions ( $\mathrm{ppbC} / \mathrm{ppb}$ ) (Tables S 3 and S 4 ) and regression equations are obtained as a function of $\mathrm{VOC} / \mathrm{NO}_{\mathrm{x}}$ ratio. In simulation, one of clear day's meteorological conditions (January 06, 2012) are used (Fig. S8) and same artificial OH radical sources are added in mechanisms like other chamber simulations. $\alpha_{i, j}$ matrix is determined when the precursor is consumed half of total consumption during the experiment $(\Delta \mathrm{ROG} / 2)$ as a representative. The resulting regression equations of $\alpha_{i, j}$ for toluene and 135 TMB are shown in Tables S5 and S6.

Table S3. Simulation conditions for the evaluation of product stoichiometric coefficient, $\alpha_{i, j}$ for toluene oxidation.

${ }^{2} \mathrm{x}$ is the ratio of VOC to $\mathrm{NO}_{\mathrm{x}}\left(\mathrm{VOC} / \mathrm{NO}_{\mathrm{x}}, \mathrm{ppbC} / \mathrm{ppb}\right)$
${ }^{\mathrm{b}} \mathrm{In} \alpha(\mathrm{j}, \mathrm{i})$, j denotes heterogeneous reactivity (fast ( F ), medium (M). slow (S). partitioning only (P), multi-alcohol (MA)) and i denotes volatility (vapor pressure) $\left(10^{-8}(1), 10^{-6}(2), 10^{-5}(3), 10^{-4}\right.$ (4), $\left.10^{-3}(5), 10^{-2}(6)\right)(\mathrm{mmHg})$ of lumping structure.

Figure S9. Model simulation for toluene SOA yields and oligomer fractions of the total organic matter $\left(O M_{A R} / O M_{T}\right)$ under various VOC/NO $\mathrm{N}_{\mathrm{x}}$ conditions.

The simulations employ the environmental condition of the experiment performed on $01 / 06 / 12$ with 30 ppb of toluene. The total OM yields were higher in lower $\mathrm{NO}_{\mathrm{x}}$ conditions and lower in higher $\mathrm{NO}_{\mathrm{x}}$ conditions, which is consistent with the results of other laboratory studies. The oligomer fraction $\left(O M_{A R} / O M_{T}\right.$, black line) to the total OM shows different pattern. The model shows that oligomer fraction was highest at $\mathrm{VOC} / \mathrm{NO}_{\mathrm{x}}$ ratio is near 10 and decrease either as $\mathrm{NO}_{\mathrm{x}}$ increases or decreases.
