13 Supplementary information

14 **Analytical method description**

15 This method covers the following groups of components:

- 16 • α-, and γ-HCH
- 17 • HCB
- 18 • *o,p'*- and *p,p'*-DDT, DDD, DDE
- 19 • *trans*- and *cis*-chlordan
- 20 • *trans*- and *cis*-nonachlor
- 21 • PCB (18, 28, 31, 33, 37, 47, 52, 66, 74, 99, 101, 105, 114, 118, 122, 123, 128, 138,
22 141, 149, 153, 156, 157, 167, 170, 180, 183, 187, 189, 194, 206, and 209)

23

24 Solvents and adsorbents were of ultra-trace analysis grade (SupraSolv, Merck, Darmstadt,
25 GER), all gases were provided by Hydro (N₂ and He, 6.0 quality, Porsgrunn, NO).

26 **Preparation of sampling equipment:** New plugs are extracted in a 2000 ml Soxhlet
27 extractor with toluene (24 h), acetone (8 h) and with toluene (8 h). Plugs, which have been

1 previously extracted after sampling, are cleaned using Soxhlet extraction with acetone (8 h)
2 and toluene (8 h). After extraction the bulk of the solvent is removed by squeezing the plugs
3 using solvent resistant lab gloves. The plugs are transferred into a desiccator and placed in an
4 oven for drying at 60° C and 100–200 mbar vacum. Following drying two plugs are placed in
5 a custom-designed PUF sampling support (DIGITEL, Hegenau, Switzerland) and sealed with
6 lids which are connected with flate-ground joint and clamps (see Figure S1). For transport and
7 storage the PUF supports are stored in aluminium boxes with tailor-made plastic foam inlays.

8 Glass fibre filters (GFF: 150 mm id, CaNo 1822-150, Whatman, Buckinghamshire, UK) are
9 heated in an oven to 450 °C (8 h). After cooling they are mounted into the filter support
10 (DIGITEL, Hegenau, Switzerland) and the support with the mounted filter were packed in
11 aluminium foil and zip-lock bag.

12

13 **Sample collection:** For the monitoring, continuous integrated weekly/7-days samples were
14 collected with a flow rate of 10 - 15 m³/h resulting in sample volumes between 2200 and 2500
15 m³. A commercially available high volume air sampling device (DHA-80, DIGITEL,
16 Hegenau, Switzerland) for separate particle and gas phase collection was used for the
17 monitoring of POPs. The particle phase was collected on glass fiber filters whereas the gas
18 phase was collected on pre-cleaned polyurethane foam plugs (PUF). Gas- and particle phase
19 samples were collected simultaneously. Flow-rate and sampling conditions were digitally
20 monitored and documented (e.g., power failures, etc) as integrated part of the sampling and
21 quality control procedure. Sector controlled sampling was performed where air masses
22 passing over the main research station were not collected in order to minimize the potential
23 for local contamination.

24 **Sample storage:** After the sampling was completed, the exposed filters (GFF and PUF) were
25 packed again in aluminium/zip lock bag (GFF) or sealed with glass lids (PUF). All exposed
26 filters/PUFs were registered and stored frozen (-20°C) between sampling and analysis,
27 however, not during air transport between Troll station and quantification. The yearly sample
28 set was shipped on the first flight every austral summer (November) to the analytical
29 laboratory in Norway by combined ship and airfreight transport.

1 **Sample preparation:** All samples were Soxhlet extracted for 12 h with *n*-hexane/diethylether
2 (90:10, v:v), firstly the GFF part of a given sample in a 50 mL Soxhlet extractor and secondly
3 the two PUFs of the same sample in a 250 mL Soxhlet extractor mounted on the same round-
4 bottom flask. Prior to extraction a mixture of 10 ng of different ^{13}C Internal Standards (IST)
5 for all congener and isomer groups analysed was added to the GFF. Volume reduction to ca.
6 500 μL was performed on a Turbovap (Caliper-Zymark, Hopkinton, MA, USA). The
7 concentrated sample was transferred to a 10–15 mL centrifuge tube, 8–10 mL conc. sulphuric
8 acid added, and placed in a rack until the next day. The hexane fraction was transferred to a
9 new centrifuge tube and 1 mL MilliQ water added drop by drop. The water phase was
10 removed and the hexane phase dried with $\frac{1}{2}$ teaspoon precleaned sodium sulfate. After
11 volume reduction, the extract was transferred to a 15 cm glass column (with stop cock) filled
12 with precleaned and preconditioned Silica (2%-w water) and a top layer of pre-cleaned
13 sodium sulfate for clean-up. After clean-up, volume of the eluate was reduced to 500 μL
14 (Turbovap) and further reduced to 100 μL under a gentle N_2 stream. Before quantitative
15 analysis, 10 ng of 1,2,3,4-tetrachloronaphthalene (TCN) was added as recovery standard
16 (RecStd, table S1–S3).

17 **Quantitative analysis:** After sample preparation, the eluates were quantitatively analysed
18 using high-resolution gas chromatography coupled to a high-resolution sector field mass
19 spectrometer as detector (HRGC/HRMS). A 6890N Agilent gas chromatograph (Agilent, Palo
20 Alto CA, USA) was coupled to an Autospec Ultima sector field mass spectrometer (Waters,
21 Milford, MA, USA). An aliquote of 2 μL of the eluate was injected into the gas
22 chromatograph in splitless mode (280 °C and 2 min splitless time). The analyses were
23 performed with maximum resolution (ca. 10 000) in Electron Impact (EI: PCBs, HCB, DDT
24 derivatives) and Negative Ion Chemical Ionisation mode NICI: OCP) for the respective
25 compounds groups. For highest sensitivity grouped single ion monitoring (SIM) was applied.
26 The detailed GC and MS parameters are given in Table S1 to S2 and the SIM groups are
27 listed in Table S3 to S5. The isotope dilution method using ^{13}C -labeled internal standards was
28 applied for identification and quantification of the target compounds.

29
30 **Quality control:** Sampling and sample storage was an integral part of the overall quality
31 control program. The responsible technicians at the Troll research station followed detailed

1 routines developed by NILU in order to avoid unwanted contamination during field work.
2 The analytical procedure used for the study was accompanied by a comprehensive quality
3 control program based on the requirements of NILU's accreditation, according to NS-EN/ISO
4 IEC 17025 (2005). The instrument limit of detection was determined (LOD) by calculating
5 the signal to noise ratio (S/N) > 3 for solvent blanks (using *n*-hexane). Extensive field and
6 laboratory blank values were analysed in order to monitor and control possible contamination
7 during sample transport and laboratory work. No evidence for contamination during sample
8 processing was found for the data presented here (no elevated values in field- and laboratory
9 blanks). All raw data are openly accessible from the NILU database (ebas.nilu.no) for
10 thorough examinations. As a general survey, monthly arithmetic mean values are listed in
11 table S4. All values below LOD were excluded from further statistical treatment (treated as
12 not detected = n.d.).

6

7 Appendix C

8 The temperature dependent partitioning onto aerosols was calculated as detailed in the CoZMoPOP2 model, using a K_{OA} -based approach and
 9 default environmental parameter settings [1]. Temperature-dependent physical-chemical properties for the selected substances included in
 10 Figure S2 were adopted from the literature [2-5].

1 **Figure S2.** Estimated percentage sorbed on aerosols within the temperature range from -50°C to 5°C.
