11	Abstract
12	
13	The Aerosol Robotic Network (AERONET) has been providing high-quality
14	retrievals of aerosol optical properties from the surface at worldwide locations for more
15	than a decade. Many sites have continuous and consistent records for more than 10 years,
16	which enables the investigation of long-term trends in aerosol properties at these
17	locations. In this study, we present the results of a trend analysis at selected stations with
18	long data records. In addition to commonly studied parameters such as Aerosol Optical
19	Depth (AOD) and Ångström Exponent (AE), we also focus on inversion products
20	including Absorption Aerosol Optical Depth (ABS), Single Scattering Albedo (SSA) and
21	the Absorption Ångström Exponent (AAE). Level 2.0 quality assured data is the primary

22 source. However, due to the scarcity of Level 2.0 inversion products resulting from the 23 strict AOD quality control threshold, we have also analyzed Level 1.5 data, with some 24 quality control screening to provide a reference for global results. Two statistical methods 25 are used to detect and estimate the trend: Mann-Kendall test associated with Sen's slope 26 and linear least squares fitting. The results of these statistical tests agree well in terms of 27 the significance of the trend for the majority of the cases. The results indicate that Europe 28 and North America experienced a uniform decrease in AOD, while significant (> 90%) 29 increases of these two parameters are found for North India and the Arabian Peninsula. 30 The AE trends turn out to be different for North America and Europe, with increases for 31 the former and decreases for the latter, suggesting opposite changes in fine/coarse mode 32 fraction. For Level 2.0 inversion parameters, Beijing and Kanpur both experienced an 33 increase in SSA. Beijing also shows a reduction in ABS, while the SSA increase for Kanpur is mainly due the increase in scattering aerosols. Increased absorption and 34 reduced SSA are found at Solar\_Village. At Level 1.5, most European and North 35 36 American sites also show positive SSA and negative ABS trends, albeit the data are more 37 uncertain. The AAE trends are less spatially coherent due to large uncertainties, except 38 for a robust increase at three sites in West Africa, which suggests a possible reduction in 39 black carbon. Overall, the trends do not exhibit obvious seasonality for the majority of 40 parameters and stations.

41

### 42 Introduction

44	Atmospheric aerosols have been recognized as an important climate forcing agent
45	(Charlson et al., 1992) and play a critical role in global climate change (IPCC, 2013).
46	The climate effect of aerosols is determined by their optical properties, including
47	scattering and absorption. Changes in these properties will thus alter the radiative forcing
48	of aerosols. Therefore, understanding the space-time variability of these optical properties
49	is essential in order to quantify the role of aerosol in recent climate variability and climate
50	change. Therefore, long-term trends are of particular interest, because they help us
51	understand the global and regional cycling of different aerosol species of both natural and
52	anthropogenic origin, as well as validate emission inventories and the representation of
53	aerosols in climate models. Aerosol trends are also critical in resolving the change of
54	surface radiation balance over the past few decades, such as global brightening found
55	over multiple locations in Europe and North America (Wild et al., 2005, 2009).
56	Previously, many studies have investigated long-term trends in aerosol loading and
57	related parameters using satellite or ground-based remote sensing data or in-situ
58	measurements. Mishchenko et al. (2007) reported a global decline in AOD since the
59	1990's found in AVHRR retrievals. Zhang and Reid (2010) studied regional AOD trends
60	using MODIS and MISR over water product and revealed regional differences in the
61	trends. Xia (2011) analyzed AOD trends using AERONET data at 79 locations and found
62	significant decreases over North America and Europe. Other studies analyzed trends in
63	visibility as an aerosol proxy (e.g., Mahowald et al., 2007; Wang et al., 2009; Stjern et al.,

64	2011), or inferred aerosol trends from solar radiation (e.g., Wild, 2009, 2012). Most of the
65	above studies focused on the primary aerosol loading indicator which is the optical depth.
66	A few also included the Ångström Exponent. However, the trends in other aerosol
67	properties, in particular, aerosol absorption, scattering and single scattering albedo,
68	remain less well known, partly attributed to the difficulty in retrieving these variables
69	using remote sensing techniques. Yet, aerosol absorption and single scattering albedo are
70	equally, or even more important in determining aerosol forcing. Changes in these
71	quantities impact heavily on both aerosol direct effect and aerosol-cloud interaction.
72	Recently, Collaud Coen et al. (2013) analyzed long-term trends in aerosol scattering and
73	absorption coefficients using in-situ measurements at US and European locations. Their
74	study indicated significant reduction in scattering coefficients for both the US and Europe,
75	with less significant reduction in absorption coefficients. These results both improve our
76	understanding of changes in aerosol optical properties and provide an assessment of
77	emission reduction policies. Atmosphere inversion products from AERONET (Holben et
78	al., 1998; Dubovik and King, 2000, Dubovik et al. 2006) involve column retrievals of
79	aerosol scattering and absorption, which complement in-situ measurements in providing
80	column optical information. In addition, the AERONET network is much more extensive,
81	covering many important aerosol source regions such as Africa, South America and Asia.
82	As a result, an analysis of long-term trends revealed by AERONET measurements is
83	desirable to better understand the recent changes in aerosol properties over worldwide
84	locations.

85	A major difficulty in using AERONET inversion products for trend analysis is the
86	uncertainty of the measurements. The accuracy of the retrievals was analyzed in
87	extensive sensitivity studies by Dubovik et al. (2000). Based on the results of these
88	studies Dubovik at al. (2002) recommended a set of criteria for selecting the high quality
89	retrieval of all aerosol parameters including aerosol absorption. These recommendations
90	were adapted as part of quality assurance criteria applied to produce the quality-assured
91	Level 2.0 inversion product (Holben et al., 2006). One of the adapted criteria excludes all
92	cases with AOD < 0.4 because <i>Dubovik et al.</i> (2000) indicated a significant decrease in
93	accuracy of retrieved aerosol parameters with decreasing aerosol optical thickness. For
94	example, the accuracy of the SSA retrieval dropped from 0.03 to 0.05-0.07 for AOD
95	values of 0.2 and less. However, the observations with AOD $< 0.4$ actually represent bulk
96	of the data for many stations. As a consequence of this AOD screening, very few stations
97	have long-term consistent Level 2.0 inversion products available. Since there is no other
98	dataset with comparable accuracy and coverage, we have therefore also included Level
99	1.5 data for the SSA, ABS and AAE parameters using the AERONET quality screening
100	except for the AOD threshold, to provide a reference global result. Moreover, due to gaps
101	in many data records and the non-normal distribution of some parameters (AOD and
102	ABS), caution must be taken when using statistical methods to estimate the magnitude
103	and significance of trends.
104	In this study, we focus on AERONET Level 2.0 AOD and AE retrievals from 90

stations and Level 2.0 inversion products from 7 stations. Level 1.5 inversion data at 44

106	additional stations are also analyzed. Two statistical methods, namely Mann-Kendall test
107	and linear least squares fitting, are used to detect the trends in order to improve the
108	robustness of the results.
109	The paper is organized as follows: Section 2 introduces the AERONET data and
110	describes data selection/quality control criteria. Section 3 introduces the analysis
111	techniques with some examples. Section 4 presents the trends for the five parameters in
112	three subsections: Level 2.0 AOD and AE, Level 2.0 SSA, ABS and AAE and Level 1.5
113	SSA, ABS and AAE. Some discussion of the results is provided in Section 5 followed by
114	a summary of the major findings in Section 6.
115	
116	2. AERONET Data
117	
118	The Aerosol Robotic Network (Holben et al., 1998) provides high quality
119	measurements of major key aerosol optical parameters at over 400 worldwide stations.
120	The direct solar radiation is used to calculate columnar AOD at $\pm 0.01$ accuracy for the
121	visible channels. Direct and diffuse measurements can also be inverted to retrieve other
122	properties including SSA and ABS (Dubovik and King, 2000, Dubovik et al. 2006). The

- 123 AOD, ABS and SSA used in the trend analysis are at 440 nm. The AE and AAE  $\alpha$
- 124 parameters are from the standard AERONET product, which are derived using AOD and
- ABS measurements at all four wavelengths in the [440, 870] nm interval, respectively, to
- 126 provide information on aerosol size and composition. The data are obtained from the

version 2 Level 2.0 direct measurements for AOD and AE, and Level 2.0 and Level 1.5inversion products for the other parameters.

129 For the purpose of our long-term trend study, we select stations purely based on the 130 availability of an extensive data record. Specifically, we first calculate monthly medians 131 of the parameters using all-point measurements. The reason for using the median instead 132 of the mean is that many optical parameters such as AOD and ABS do not follow a 133 normal distribution, in which case the median is a better representation than the mean. A 134 monthly median is considered valid only if there are more than 5 measurements for that 135 month. To ensure a continuous time series, we require the data record to have at least 6 136 vears of measurements with no less than 9 monthly data points for each year during the 2000 to 2013 period. For the direct sun measurement, 90 stations are selected. While for 137 138 the inversion product, only 7 stations have gualified Level 2.0 data, and they are mostly 139 located in heavily polluted regions in the Northern Hemisphere. The Level 2.0 quality 140 assurance for the inversion product enforces several thresholds. In particular, only 141 measurements made at solar zenith angle  $> 50^\circ$ , sky error < 5% and 440 nm AOD > 0.4142 are considered accurate (Holben et al., 2006). However, the AOD threshold excludes the 143 majority of the stations, especially those located in North America, Europe and the 144 Southern Hemisphere, where AOD is usually low. For a preliminary examination of 145 changes in aerosol absorption properties worldwide, which is still limited in literature, we 146 make use of Level 1.5 data with some screening. Specifically, the solar zenith angle and 147 sky error requirements are applied to all point Level 1.5 measurements, but not the AOD

148	threshold. Also we only select Level 1.5 data when there was coincident (within $\sim 1$
149	minute) Level 2.0 AOD data available. This ensures the accuracy of input sky radiances.
150	Forty four Level 1.5 stations are then selected, covering most of North America, Europe
151	and some places in the Southern Hemisphere. The locations and number of available
152	monthly medians used for the analysis are listed in Table 1 (AOD and AE) and Table 2
153	(SSA, ABS and AAE). The distributions of the stations are displayed Figure 1. All
154	stations on Figure 1 are used for AOD and AE analysis, the stations marked by green are
155	also used for Level 2.0 SSA, ABS and AAE analysis, and those marked by yellow are
156	used for Level 1.5 analysis.
157	
158	3. Trend Analysis Methods
159	
160	Detecting trends in time series data is a non-trivial task, especially when many of the
161	parameters are not normally distributed and autocorrelation associated with seasonality

162 usually exists in the record. To determine and estimate annual trends, a two-step approach

163 is taken here. First, we apply a 12-month running mean to the de-seasonalized data (by

164 removing multi-year averaged seasonal cycle) to manually observe the underlying

165 smoothed structure. Next, two statistical methods – Seasonal Mann-Kendall (MK) test

associated with Sen's slope and linear least squares fitting of the de-seasonalized data, are

167 used to further test and estimate the trends. Moreover, we also estimate the trend using

the MK and least squares methods for each season in order to examine whether there is

obvious seasonality in the trends. The two trend analysis techniques are described in thefollowing two subsections.

171

## 172 3.1 Mann-Kendall Test and Sen's slope

173

174 The Mann-Kendall statistical test (Mann, 1945; Kendall, 1975) is a non-parametric 175 test to identify whether monotonic trends exist in a time series. The advantage of the 176 nonparametric statistical tests over the parametric tests, such as the *t*-test, is that the 177 nonparametric tests are more suitable for non-normally distributed, censored, and missing 178 data, which are frequently encountered in the AERONET data record. However, many 179 time series of aerosol parameters may frequently display statistically significant serial 180 correlation, especially those associated with seasonal variability. In such cases, the 181 existence of serial correlation will increase the probability that the MK test detects a 182 significant trend (von Storch, 1995; Yue et al., 2002; Zhang and Zwiers, 2004). It is 183 therefore necessary to "pre-whiten" the time series by eliminating the influence of AR(1) 184 serial correlation before performing the test. Yue et al. (2002) indicate that directly 185 removing the AR(1) component from the raw time series also removes part of the 186 magnitude of the trend and proposed a pre-whitening scheme by first removing the linear 187 trend form the time series by  $X_{t} = X_{t} - T_{t} = X_{t} - bt$ 188 (1)

189 where *b* is the slope of the trend estimated using Sen's method (*Sen*, 1968), and then

190 removing the AR(1) component from  $X_t^{'}$  by

191 
$$Y'_t = X'_t - r_1 X'_{t-1}$$
 (2)

192  $r_1$  is lag-1 autocorrelation, and finally adding the trend back by

$$193 Y_t = Y_t + T_t (3)$$

- 194 The blended time series  $Y_t$  preserves the true trend but is no longer influenced by the
- 195 effect of autocorrelation. Furthermore, *Hirsch et al.* (1982, 1984) extended the MK test to
- take seasonality into account, and estimated annual trend as the median of seasonal trends.
- 197 Here we adopt the *Yue et al.* (2002) pre-whitening scheme and perform the Seasonal MK
- 198 test on the pre-whitened times series  $Y_t$ . Two-tailed tests at both 95% and 90%
- significance level were applied to test either an upward or downward trend.
- 200 To estimate the true slope b of the trend, we use the non-parametric procedure 201 developed by *Sen* (1968) as follows:

202 
$$b = \operatorname{Median}(\frac{X_i - X_j}{i - j}) \forall j < i$$
 (4)

A 90% significance level is applied to calculate the upper and lower limits of the confidence interval of the slope. Compared to other slope estimators such as linear regression coefficient, the Sen's slope is much less sensitive to outliers, which is particularly suitable for Level 1.5 data in which outliers occasionally appear.

208 3.2 Linear Least Square Fitting

209

211 Weatherhead et al. (1998). The data time series is modeled by fitting the following 212 relationship with a least square approximation:  $Y_t = Y_0 + bt + N_t$ 213 (5) $Y_t$  is the de-seasonalized monthly median time series, b is the linear trend,  $Y_0$  is the 214 215 offset at the start of the time series, and  $N_t$  is the noise term. The noise term  $N_t$  is 216 further modeled as an AR(1) process:  $N_t = \phi N_{t-1} + \varepsilon_t$ 217 (6) 218 Weatherhead et al. (1998) suggested that the standard deviation of the yearly trend  $\sigma_b$ 219 can be estimated as  $\sigma_b \approx \frac{\sigma_N}{n^{3/2}} \sqrt{\frac{1+\phi}{1-\phi}}$ 220 (7)221 where  $\sigma_N$  is the standard deviation of  $N_t$ , and *n* equals the total number of years in the series. Weatherhead et al. (1998) also found that if  $|b/\sigma_b| > 2$ , the trend is significant at 222 223 95% significance level. And 90% level is found for  $|b/\sigma_b| > 1.65$  (*Hsu et al.*, 2012). In 224 large number of application, the least squares approach is based on the Gaussian 225 distribution of uncertainties. However, a number of studies have pointed out that this 226 assumption is often not appropriate for the analysis of some properties derived in remote 227 sensing applications. For example, O'Neill et al. (2000) suggested using the lognormal 228 distribution as a reference for reporting aerosol optical depth statistics. Moreover,

210 Linear trends and their significance level are also estimated using the method by 229 Dubovik and King (2000) and earlier Dubovik et al. (1995) have pointed to the 230 importance of using log-normal distribution as a noise assumption in statistically 231 optimized fitting of positively defined physical characteristics. Indeed, the curve of the 232 normal distribution is symmetrical and the assumption of a normal probability density 233 distribution necessarily implies the possibility of negative results arising even in the case 234 of physically nonnegative values (e.g. intensities). For nonnegative characteristics, this 235 assumption is clearly more reasonable. First, log-normally distributed values are 236 positively-defined and a number of theoretical and experimental reasons show that for 237 positively defined characteristics the log-normal curve (multiplicative errors, *Edie et al.* 238 (1971)) is closer to reality than normal noise (additive errors, a statistical discussion can 239 be found in *Tarantola*, 1987). Therefore in the present study, the least squares fitting for 240 AOD, and ABS is performed on the logarithm of the data. 241 242 **3.3 Analysis Example** 243 244 Here we show an example of the trends observed by running mean, and estimated

245 using MK/Sen's slope and least squares fitting, using Level 2.0 direct measurements and

inversion products from the Beijing station. Figure 2 displays the de-seasonalized time

- series with 12-month running mean, results of MK test and Sen's slope and linear trend
- from least squares fitting for the six parameters. According to Figure 2, three of the

249 parameters, ABS, SSA and AAE exhibit statistically significant (> 90% and the same

250	hereafter) trends, from both MK and least squares fitting results, while the other
251	parameters do not have significant trends. For ABS, even with a large gap in the time
252	series from 2007 to 2009, a continuous decrease can still be observed from the smoothed
253	time series (black curve in the top panel). The MK test and least squares fitting results are
254	also consistent in indicating significant negative trends. Similarly, consistent increasing
255	trends are found for SSA. Since AOD does not have significant trends, the decrease in
256	ABS is responsible for the increase in SSA at Beijing. The AAE parameter also shows an
257	increase, although the increase mostly lies in the later part of the time series. Since the
258	mixing of black carbon with other species such as dust and organic carbon tends to
259	increase the AAE value (Russell et al., 2010), this result may imply a reduction in black
260	carbon fraction, which is consistent with the decrease in ABS and increase in SSA. The
261	normal probability plots (normplots) of the least squares fitting residuals are also
262	presented in Figure 3, which shows that the residuals follow a normal distribution and
263	thus verifies the validity of least squares fitting.
264	
265	4.Results
266	
267	In this section, we focus on presenting and discussing global maps showing the
268	magnitude and significance of the trends of the six variables at each station in the main
269	text, while the plots of the trend analysis at each individual station are included in the
270	supplementary material. Only statistically significant trends (> 90%) are indicated in the

271	figures. In addition, Table 1 and 2 list the magnitude and significance of the trends at all
272	stations from the MK and least squares analysis. The magnitude is shown as the Sen's
273	slope while the results of least squares fitting are indicated as positive or negative. This is
274	due to the fact that least squares fitting is performed on the logarithm of some parameters
275	so that the magnitude of the trend is not directly comparable to the Sen's slope.
276	Comparing the results for MK and least squares fitting (Tables 1 and 2), we see that the
277	two techniques yield consistent results in the significance for the majority of the cases. In
278	the following discussion, we only present trends that are determined to be significant by
279	both methods as we consider these trends to be the most robust. Note that trends for the
280	Level 2.0 AOD globally, and for SSA, ABS at the seven Level 2.0 stations are the most
281	reliable, thus emphasis is given to these results.
282	
283	4.1 AOD and AE Trends
284	
285	Statistically significant 440 nm AOD trends at the 90 selected stations are presented
286	in Figure 4. The AERONET AOD measurements are highly accurate, therefore the AOD
287	trends are the most robust among the parameters analyzed. Only trends above 90%
288	significance level are shown, and larger dots indicate trends above 95% significance level.
289	The majority of the stations with significant trends exhibit negative trends in AOD,
290	including most stations in North America, Europe, one biomass burning site in South
291	America (CUIABA-MIRANDA) and two sites in Japan (Osaka and Shirahama). The

292	largest decreases are found over West Europe, reaching $\sim$ -0.1/decade. Strong positive
293	trends are found at Kanpur in North India, and Solar_Village in the Arabian Peninsula.
294	We also examine the trend for each season, using the MK and least squares methods
295	on the seasonal mean time series. The results are shown in Figure 5. In general, the trends
296	are most prominent during the spring (MAM) and summer (JJA) seasons, which usually
297	correspond to the seasons with the highest aerosol loading for many locations in the
298	Northern Hemisphere. The patterns on each seasonal trend map agree, in general, with
299	the global results. Some stations only exhibit significant trends for certain seasons. For
300	example, the European and North American stations mostly show significant decreasing
301	trends for the spring (MAM), summer (JJA) and fall (SON). For India, significant trends
302	are found during the fall and winter (DJF). By further examining the time series (figures
303	in the supplementary materials), it is found that the seasons without significant trends
304	usually have frequent missing data, which affects or even precludes the detection of
305	trends. Overall, the similarity between the four panels in Figure 5, and between Figure 5
306	and Figure 4, respectively, indicates that there is no obvious seasonality in the AOD
307	trends.
308	In addition to column aerosol loading, the Ångström Exponent parameter is an

indication of the contribution of fine and coarse mode aerosols and can also be potentially
useful to infer aerosol composition. The global AE trends are shown in Figure 6. It is
interesting to note that while AOD decreased uniformly for both North America and
Europe, there AE trends are opposite. North America generally exhibits positive trends

313 while coherent negative trends are found for Europe. This result suggests a change in the 314 aerosol composition. The AOD reduction in Europe might be due to reduced fine mode 315 anthropogenic emission, while that for North America might be related to a reduction in 316 natural sources such as coarse mode mineral dust. The AE decrease for Arabian 317 Peninsula, a major dust source, is consistent with AOD increase, suggesting an increase 318 in dust emission. And the weak positive trend at Kanpur, North India suggests increased 319 anthropogenic aerosols are likely the contributor to the positive AOD trend. The seasonal 320 AE trends are shown in Figure 7. Like AOD, the trends for the four seasons are also 321 consistent with annual trends. However, note that different from AOD, which exhibits the 322 most prominent trends in the spring and summer, most AE trends are found during the 323 winter season (DJF). Yet winter usually has the minimum aerosol loading for many 324 Northern Hemisphere locations. The uncertainty in the AE parameter is significantly 325 higher than AOD, especially at low AOD conditions. According to Kato et al. (2006), the 326 uncertainty in the AE parameter can be estimated as

327 
$$\Delta AE = \left[\frac{\sum_{i=1}^{n} e_i^2}{(n-1)\sum_{i=1}^{n} (\ln \lambda_i - \overline{\ln \lambda})^2}\right]^{\frac{1}{2}}$$
(8)

328 where  $e_i$  is the error of the Ångström relation, n is the number of wavelengths  $\lambda$ 329 used to calculate AE, and  $\overline{\ln \lambda}$  is the average of the logarithm of the wavelengths. The 330 ratio  $\frac{\varepsilon_i}{AOD_i}$  is used to represent  $e_i \cdot \varepsilon_i$  is the uncertainty of AOD and is specified as

331 0.01 here. Using Equation (8) and spectral AOD measurements made at the GSFC station

332	during the study period, we found that the AE uncertainty during the winter season is
333	0.56 when the 440 nm AOD average is 0.08, while that for the summer is only 0.15 when
334	AOD average is 0.33. Similar differences in the uncertainty of AE as a function of season
335	should be expected for most Northern Hemisphere stations with similar seasonal cycles.
336	Therefore, the AE trends at the low AOD conditions such as Northern Hemisphere winter
337	must be evaluated in with the context of these increased uncertainties. The same applies
338	to the South America trends during non-peakAOD seasons of summer and winter.

339

#### 340 4.2 SSA, ABS and AAE Trends Using Level 2.0 Data

341

342 Single scattering albedo and absorption optical depth are closely related and both 343 indicate the absorption properties of aerosols. These two parameters play even more 344 important roles in aerosol forcing, as the changes in ABS or SSA not only alter direct 345 forcing, but also have potential impact on aerosol-cloud interaction if the changes are 346 associate with aerosol composition change such as trends in black carbon fraction. 347 Additionally, the AAE parameter, defined as the wavelength dependence of ABS:  $AAE = -\log(ABS_{\lambda_1} / ABS_{\lambda_2}) / \log(\lambda_1 / \lambda_2)$ 348 (9) where  $ABS_{\lambda_1}$  and  $ABS_{\lambda_2}$  are aerosol absorption optical depth at two wavelengths  $\lambda_1$ 349 350 and  $\lambda_2$ , respectively, is also an indicator of aerosol composition, and is determined by 351 the mixing of different absorbing species including black carbon, dust and organic carbon 352 aerosols. We therefore examine these three parameters together.

353	The SSA, ABS and AAE trends for the seven qualified Level 2.0 stations are
354	presented in Figure 8. All of these stations are located in the Northern Hemisphere and
355	are located in major aerosol source regions, including the dust dominated region of the
356	Arabian Peninsula (Solar_Village) and West Africa (Dakar, IER_Cinzana and
357	Banizoumbou) and heavily polluted areas in North India (Kanpur) and North China
358	(Beijing and XiangHe). Both Beijing and Kanpur show positive SSA trends while
359	Solar_Village displays a negative trend (Figure 8a). Beijing, as well as a nearby station –
360	XiangHe, also has decreased ABS. Recall that no significant AOD trends are found for
361	Beijing (Figure 4), the reduction in absorption should be responsible for the SSA increase.
362	East China has been considered as a region of increased aerosol loading in previous
363	studies (e.g., Wang et al., 2009; Zhang and Reid, 2010; Hsu et al., 2012), here
364	AERONET data indicate that aerosol absorption has actually declined over the past
365	decade for at least two locations. Nonetheless, the ability of only two close by stations to
366	represent larger-scale patterns is still limited. No significant ABS trend is found for
367	Kanpur. Because this station exhibits a strong increase in AOD (Figure 4), the positive
368	SSA and AOD trends should be mainly attributed to increased fraction of scattering
369	species, such as sulfates and nitrates. The Solar_Village station also has increased AOD
370	(Figure 4), and a corresponding increase in ABS as well. Because dust is the primary
371	aerosol species at this location which has strong shortwave absorption, the positive ABS
372	and AOD trends, and negative SSA trends consistently suggest an increase in dust
373	activities. With respect to the AAE, positive trends are observed for Beijing and the three

374	stations from West Africa, while Kanpur shows a negative trend. The theoretical value of
375	AAE for black carbon is 1, and the value increases in the presence of dust and organic
376	carbon (Bergstrom et al., 2002; Russell et al., 2010). The AAE increase in Beijing might
377	be associated with decreased black carbon fraction, which is consistent with previous
378	inferences from the AOD, SSA and ABS trends. The positive AAE trends for West
379	Africa might be associated with increased dust fraction, which tends to raise the AAE
380	value. However, as no spatially coherent AOD, or ABS trends are found over this region,
381	the AAE trends are subject to question. The AAE trend for Kanpur seems to suggest an
382	increase in black carbon fraction, which appears controversial to AOD and SSA trends.
383	Note that the AAE parameter has even larger uncertainty levels than the AE, owing to the
384	smaller ABS values and large uncertainties at low aerosol loading. Giles et al. (2012)
385	performed a series of sensitivity of the AAE parameter by perturbing SSA using
386	AERONET measurements, and found that AAE can vary by $\pm 0.6$ for dust sites with
387	$\pm 0.03$ perturbation in SSA which is the uncertainty level for this parameter at Level 2.0.
388	Therefore, the AAE trends alone are not sufficient to infer aerosol composition changes
389	and need to be evaluated with other information such as AE and ABS.
390	Seasonally, the SSA and ABS trends are highly consistent with the annual trend for
391	Beijing and Solar_Village (Figure 9). Significant decreases in ABS and SSA are observed
392	at Beijing for all seasons. This is a sign of changes in local aerosol source rather than
393	seasonal transport. For Solar_Village, the trend is absent in winter but significant for all
394	the other three seasons. The AOD values are lowest in winter at this station, and the

395	absence of the trend is primarily attributed to the lack of Level 2.0 data at these low AOD	
396	conditions (see supplementary material for the time series). At Kanpur, again no	
397	significant change in ABS is found, while the increase in SSA is only observed for the	
398	fall and winter. The seasonality of SSA trends is consistent with previously showed AOD	
399	seasonal trends (Figure 5), which is due to the frequent missing data during the spring	
400	and summer. One the other hand, the seasonality of the trends also indicates possible	
401	changes in anthropogenic aerosol emissions, the dominant aerosol type over North India	
402	during the post-monsoon and winter season (e.g., Corrigan et al., 2006). The positive	
403	trend in AAE is also present in all seasons, supporting the argument of decreased black	
404	carbon fraction. The seasonality for the three West Africa stations, however, is not	
405	consistent. Dakar shows positive trends during the spring, summer and fall, IER_Cinzana	
406	for the winter, while Banizoumbou even displays a negative trend during the fall. This	
407	spatial discrepancy further confounds the understanding of the results. Considering the	
408	large uncertainty in the AAE, more information, such as that from in-situ measurements	
409	of aerosol physical and optical properties, is needed to fully resolve the change in aerosol	
410	composition.	

411

# 412 4.3 SSA, ABS and AAE Trends Using Level 1.5 Data

413

414 As seen from last section, only seven stations have sufficient Level 2.0 inversion415 data for long-term trend analysis. The location and aerosol types of these stations are far

416	from enough to represent aerosol variability on a global basis. Observations at many
417	other places are needed to address interesting questions such as the effects of pollution
418	control measures taken at developed regions including Europe, North America and Japan,
419	and changes in biomass burning emissions in the Southern Hemisphere. Although ideally
420	we would prefer to use Level 2.0 data only, the AOD threshold of 0.4 applied to the data,
421	as required by the quality assurance criteria (Holben et al., 2006), eliminates the bulk of
422	the data, especially for the above mentioned regions where aerosol loading is typically
423	low. In Figure 9 we plot the distribution of AERONET AOD (from Level 2.0 direct sun
424	measurements) for the globe and five regions, using the stations selected for this study.
425	The small panel in the upper right corner of each larger panel shows the enlarged
426	distribution for the [0, 0.5] AOD interval, and the threshold value of 0.4 is marked by
427	black dashed lines. We can clearly see that the AOD $> 0.4$ portion only captures the tail
428	of the AOD distribution, while the bulk of the data fall between 0 and 0.4. Even for
429	Africa and Asia, where AOD are, in general, larger, the 0.4 cut-off will still eliminate
430	roughly 75% of the data. Since currently there are no other SSA or ABS measurements
431	with comparable spatial and temporal coverage to AERONET, here we also show the
432	results of an analysis of the more uncertain Level 1.5 inversion products in order to
433	provide greater spatial coverage, which may serve as a reference for future studies when
434	better quality data become available. However, the readers should keep in mind that
435	Level 1.5 data are subject to larger uncertainty when interpreting these results. Only

436 annual trends are shown. Seasonal trend maps can be found in the supplementary437 materials.

438	Figure 10 shows the global SSA, ABS and AAE trends for Level 1.5 data. The seven		
439	Level 2.0 stations are also included but Level 1.5 data are used when producing Figure 10.		
440	This is for the purpose of evaluating the effect of AOD cut-off on the trend estimate.		
441	Globally, positive SSA trends are found at the majority of the stations, in particular,		
442	Europe, North America and Asia. Correspondingly, ABS is found to have decreased over		
443	these regions, with the strongest decrease over Europe reaching $\sim$ -0.03/decade.		
444	Solar_Village and three Southern Hemisphere stations exhibit negative SSA and positive		
445	ABS trends. The AAE trends are less spatially coherent, which is more likely due to		
446	larger uncertainty associated with that parameter. Moreover, by comparing Figure 11		
447	with Figure 9 for the seven Level 2.0 stations, we find that the sign and significance of		
448	the trends are highly consistent, albeit the absolute magnitudes may differ due to changes		
449	in sampling (Note the color scale for Figure 8 and Figure 10 are different to		
450	accommodate additional Level 1.5 stations with larger trends). One can further refer to		
451	the supplementary materials and compare the Level 1.5 and Level 2.0 time series for		
452	these stations.		
453	Figure 10 is produced without any AOD thresholds. Only solar zenith angle and sky		
454	error criteria are used to screen the data. As the errors in these parameters, especially the		
455	SSA and AAE, increases as AOD becomes lower, we further repeat the analysis using an		
456	intermediate AOD threshold of 0.2 to increase some reliability. However, this screening		

457	results in a loss of roughly 60% of the data, and only 12 stations are left with sufficient
458	data for analysis. The SSA, AAE and ABS trends for these stations also agree with their
459	Level 1.5 trends without screening (Figure 10). The Level 2.0 trends at the stations shown
460	in Figure 8 are also consistent with Figure 10. The only exception is the Banizoumbou
461	station where SSA trends become insignificant at Level 2.0. In fact, Dubovik et al. (2000)
462	performed a series of sensitivity studies and while they suggested a drop in the accuracy
463	of AERONET retrievals at lower AODs, they did not find any biases due to assumptions
464	in the retrieval model.
465	The consistency in Level 1.5, Level 1.5 screened with $AOD > 0.2$ and Level 2.0
466	trends, together with spatial coherency of the Level 1.5 trends for North America and
467	Europe increases our confidence in the trends estimated using Level 1.5 data. However,
468	neither the Level 2.0 nor the Level 1.5 results should be considered to represent the
469	ground truth. Although Level 2.0 data are accurate, the analysis is biased towards large
470	aerosol loading places and conditions, while missing some other important information.
471	A typical example is measurements at Island stations which are more representative of
472	global background aerosol and are important in understanding aerosol climate forcing,
473	yet the AODs are usually too low for the inversion products to be reliable. Therefore,
474	improvements in the AERONET data quality control are needed to ensure data accuracy
475	without losing too much spatial and temporal coverage. The spatial correlation of the
476	measurements, such as the consistent trends for all stations in Europe shown above, might

477 be a helpful factor, although this information is only available for limit places where the478 AERONET network is sufficiently dense.

**5. Discussion** 

482	The significant decline found in AERONET AOD over Europe, North America and
483	Japan is consistent with studies using satellite remote sensing products (e.g., Zhang and
484	Reid, 2010; Hsu et al., 2012) and visibility data (Wang et al., 2009), and independent
485	studies using Level 2.0 AERONET direct beam retrievals (Xia et al., 2011; Yoon et al.,
486	2012). The sign of the Level 1.5 ABS and SSA trends are also in good agreement with
487	trends in aerosol scattering and absorption coefficients derived from in-situ
488	measurements reported by Collaud Coen et al. (2013), although Collaud Coen et al.
489	(2013) suggested a stronger decline in scattering coefficients for North America than
490	Europe, and also less significant trends in absorption than scattering, while the
491	AERONET data indicate significant decreases in both scattering and absorption, and
492	comparable trends for North America and Europe. These differences may stem from
493	several factors. For example, Collaud Coen et al. (2013) utilizes surface in-situ sampling
494	data while the AERONET data represent the atmospheric column. Also, most of the sites
495	in Collaud Coen et al. (2013) are remote sites while many of the selected AERONET
496	stations are urban. The timing of these trends also appears to be in line with emission
497	control measures that have taken place in Europe and North America during the past

498	decades. In the US, PM 2.5 has been estimated to have been reduced by 50% and $SO_2$ by
499	55% (EPA, 2011). Murphy et al. (2011) found significant decreases in both PM 2.5 and
500	elemental carbon using data from the IMPROVE network. Reductions in PM 2.5 and $SO_2$
501	are also reported for Europe (Tørseth et al. 2012), although the decrease is weaker than
502	that found for the US.
503	The positive SSA trends found over East Asia (East China and Japan) agree with the
504	results of a previous study by Lyapustin et al. (2011) also using AERONET data and with
505	the results of an analysis of independent measurements by Kudo et al. (2010). The
506	reduction of ABS for the China stations, especially Beijing, seems somewhat
507	controversial in light of the trends in emission inventories. For example, Lu et al. (2011)
508	indicated an increase in $SO_2$ emission in China of 62% from 2000 to 2006, with a
509	decrease of 9.2% from 2006 to 2010, while black carbon and organic carbon emissions
510	increased by 72% and 43% respectively, from 2000 to 2010. Zhang et al. (2009) also
511	suggested emission growth by 13-55% from 2001 to 2006 for most species including $SO_2$
512	and black carbon. As, the results presented here are only from two close by stations:
513	Beijing and XiangHe, the representativeness of the results are quite limited. Moreover,
514	the aerosol properties in Beijing are perturbed by the air quality control measures during
515	the Olympic games (e.g., Cermak and Knutti, 2009; Zhang et al., 2009; Guo et al., 2013),
516	which may be one of the reasons for the observed decline in ABS. However, difficulty
517	arises as most of the AERONET stations in China were established in recent years and
518	their records are not long enough for trend analysis, while satellite remote sensing

519 techniques are not capable in retrieving absorption properties. More observation-based

- trend analyses for China may become possible in the next few years when more of the
- 521 stations will have longer-term measurements.
- 522 The positive AOD trends found at Kanpur, India, are consistent with studies using
- 523 satellite remote sensing products (*Dey and Girolamo*, 2011; *Ramachandran et al.*, 2012),
- and independent ground-based measurements (*Babu et al.*, 2013). The AERONET results
- 525 presented here imply that scattering aerosols are primarily responsible for this increase in
- 526 AOD. The increase in aerosol scattering also largely agrees with positive trends in SO<sub>2</sub>
- 527 over India, as reported by *Lu et al.* (2013) and *Mallik et al.* (2013).
- 528 The increase in AOD at the Solar\_Village station is corroborated by satellite
- 529 observation (*Hsu et al.*, 2012; *Chin et al.*, 2014) and transport model results (*Chin et al.*,
- 530 2014). AERONET data further verify that the change is due to increased dust emission
- 531 with negative AE trend, negative SSA and positive ABS trend.
- 532 Particular attention should be paid to the trend in SSA as revealed by AERONET
- 533 data. Whether changes in atmospheric aerosol loading will induce a heating or cooling
- effect on the climate heavily depends on the SSA parameter. It is believed that there is a
- 535 critical value of the SSA above which aerosols produce a negative forcing (cooling), and
- below which the aerosol produce a positive forcing (warming). *Hansen et al.* (1997)
- 537 concluded from GCM experiments that aerosols with SSA up to 0.9 would lead to global
- 538 warming, and that the anthropogenic aerosol feedback on the global mean surface
- temperature is likely to be positive. *Ramanathan et al.* (2001) indicated that for

540	SSA<0.95, aerosol net forcing can change from negative to largely positive depending on		
541	aerosol height, surface albedo and cloud conditions. Moreover, the change in this		
542	parameter implies changes in the relative fraction of absorbing species (mainly black		
543	carbon) with respect to scattering aerosols, which may have broad impact on their total		
544	radiative effect. Ramana et al. (2010) found that the warming of black carbon strongly		
545	depends on the ratio of black carbon to sulfate aerosols. Therefore, the change in SSA for		
546	many locations implies a potentially larger change in the aerosol forcing. In particular,		
547	while the recent increase in surface radiation, or global brightening, found for Europe,		
548	North America and Japan have been largely attributed to the reduction of total aerosol		
549	loading, the increase of SSA could also contribute to this trend (Kudo et al., 2010).		
550	Another important consequence of trends in SSA is the impact on satellite retrieved		
551	trends of aerosol properties. As most satellite retrieval algorithms assume constant SSA		
552	values for the aerosol models, systematic changes in SSA over time may produce		
553	spurious tendencies in the retrieved AOD (Mishchenko et al., 2007). Lyapustin et al.		
554	(2012) indicated that the temporal change in the bias between MODIS and AERONET		
555	AOD over Beijing can be explained by the increase of SSA at this station. Mishchenko et		
556	al. (2012) showed that in the AVHRR AOD retrieval, decreasing SSA by 0.07 from the		
557	start to the end of the data record could eliminate the downward trend in the data.		
558	Therefore, the trends in SSA revealed by AERONET measurements should be taken into		
559	account in the retrieval algorithms to yield a more accurate representation of temporal		
560	changes in aerosol loading.		

561	Admittedly, the AERONET data are not perfect. Several limitations may affect the
562	accuracy of the trend analysis presented here. In addition to the larger uncertainties
563	associated with low AOD conditions for AE, SSA, ABS and AAE, the spatial
564	representativeness of the stations is also a factor that should be considered when
565	evaluating the trends at each individual station. Many of the stations selected here are
566	urban sites, where aerosol properties tend to be highly variable due to the influence of
567	many local emission sources. For example, some nearby stations in Europe have opposite
568	trends in the ABS and SSA, which suggests that they may be dominated by different local
569	sources and aerosol types. To address this problem, more efforts should be given to
570	maintaining long-term, continuous monitoring of aerosol properties at remote locations.
571	Nonetheless, to date, AERONET is the most extensive ground-based aerosol observation
572	network with high retrieval accuracy, and the trends presented here are significant by
573	both MK test and least squares fitting methods. Both these factors improve the robustness
574	of the results.
575	

## 576 **6.** Conclusions

577

578 In this study, we present the results of a trend analysis of key aerosol properties 579 retrieved from AERONET measurements. Although trends in total aerosol loading such 580 as AOD have been extensively investigated, fewer studies are found for the absorption 581 and scattering properties. This work therefore serves as a reference for evaluating recent changes in aerosol forcing and the assessment of emission inventories and emissioncontrol measures. The major conclusions are summarized below:

584	_	Significant decreases in AOD are found for most locations, in particular, North
585		America, Europe and Japan. The Kanpur station in North India and
586		Solar_Village in the Arabian Peninsula experienced increases in AOD;
587	_	The AE parameters exhibit positive trends over North America but negative
588		trends over Europe, suggesting decreases in natural and anthropogenic aerosols
589		are responsible for the AOD reduction over these two regions, respectively.
590	_	AERONET Level 2.0 inversion products reveal increases in SSA and decreases
591		in ABS for Beijing and Solar_Village. Positive SSA trend is also observed for
592		Kanpur but is attributed to the increase in scattering aerosols.
593	_	Level 1.5 inversion data are also analyzed for a broader spatial coverage.
594		Spatially uniform increases in SSA are found for Europe and North America,
595		associated with decreases in ABS. For the seven stations with qualified Level
596		2.0 data, the trends are consistent at Level 1.5, Level 1.5 with AOD>0.2
597		threshold and Level 2.0.
598	_	No obvious seasonal dependence is found for any of the trends;
599	Fina	ally, it is important to restate that Level 1.5 results presented here are subject to
600	large un	certainty. Moreover, except for the AOD, the other parameters also have large
601	uncertai	nties at low AOD conditions even for Level 2.0. The exceptions are sites with
602	very hi	gh AOD such as Beijing, Kanpur, XiangHe, IER Cinzana, Banizoumbou

603	Solar_Village and Dakar, where very high AOD levels allow for accurate retrievals of all
604	parameters analyzed. With the further development of the AERONET algorithm, such as
605	the release of version 3 data in the near future, a more accurate estimation will become
606	possible.
607	
608	Acknowledgements
609	
610	We thank the AERONET team, especially the PIs of the 90 selected stations, for
611	providing the data used in this study. The AERONET data is obtained from the
612	AERONET website http://aeronet.gsfc.nasa.gov/. This study is funded by NASA climate
613	grant 509496.02.08.04.24. Jing Li also acknowledges Hal Maring and the NASA
614	Radiation Science program for providing funding for this investigation.
