Thanks for replying my comment. Your new approach for estimating the effective uptake rate looks promising and should provide more realistic results.

There are still problems with the equations for the particle radius. In the article of Fouquart et al. (1990), the effective cloud particle radius is given (in micrometers) as  $4 + 11 \cdot w$ , where  $w$  is the liquid water *content* in grams per cubic meter, not the liquid water path. Using LWP instead of LWC cannot give the correct answer.

Regarding ice clouds, I still can't get realistic numbers from the equations. I would recommend that all units be specified to make things more clear. Also, is  $A$  in Eq. (5) equal to  $A_{\text{ice}}$  in Eq. (4) or should it be multiplied by 10 as discussed in the text?
