

Interactive comment on “Variability of NO_x in the polar middle atmosphere from October 2003 to March 2004: vertical transport versus local production by energetic particles” by M. Sinnhuber et al.

M. Sinnhuber et al.

miriam.sinnhuber@kit.edu

Received and published: 2 June 2014

The authors would like to thank the reviewer for his/her helpful comments. Below are all the comments followed by replies; in “” are changes made to the text of the paper.

Specific Comments p6, line 1. For people who wish to repeat any of this work, it would be helpful to cite a reference for the averaging kernels.

The description of the averaging kernel criterion in section 2 (MIPAS data) has been

C3058

changed to:

“Where daily averages have been used, NO, NO₂ and CO data with low sensitivity have been excluded by applying a threshold to the mean value of the averaging kernel (AK) matrix (Rodgers, 2000) diagonal element. The AK diagonal elements represent a measure of the sensitivity of the retrieval at a given profile grid point to the “true” vmr. Values close to zero (here <0.03) indicate that there is no significant sensitivity to the abundance at the corresponding altitude.”

p10, line 8. Will transport and mixing really act on CO and NO_x in the same manner? Doesn't this depend on vertical and horizontal gradients in the two constituents, which are not the same?

This is correct, and the reason we do not expect (and indeed do not see) a linear correlation in Fig 6.

Figure 6. I suggest adding color scales that denote the dates of the various colors in the two panels.

Done

p10, lines 16-21. On the basis of the CO/NO_x relationship, the authors conclude that the high values of NO_x below 70 km in late January are most likely due to subsidence of air, rather than direct production. I believe that the rationalization is that since the NO_x values in air that had descended to 70 km were already high by 19 January – before the storms – there is no need to invoke a direct production source to explain them. This was not obvious at first reading, though, so if I am correct, a more explicit discussion would be helpful. Particularly important is to point out that even though the high CO / high NO_x correlation *by itself* cannot rule out direct production (since the production could have occurred in air that had already descended), the fact that high NO_x existed in the descended air prior to the geomagnetic storms is sufficient justification for the conclusion. (Of course, if that is not what is meant, the discussion should be modified

C3059

accordingly).

There are two arguments here: both NO_x and CO increase at the same time, during a relatively short time-interval between January 14 and January 19. The increase of both NO_x and CO at the same time suggests downwelling as a source. Additionally, the largest amounts of both NO_x and CO are reached on January 19, several days before a large storm on January 22; the large geomagnetic storm on January 22/23 was thus not the source of the large NO_x values, as suggested, e.g., by Renard et al., 2006. The paragraph has been changed to

“The upper branch of the relationship with CO values >10 ppm and NO_x values >700 ppb appears only after 14 January, at altitudes above 60 km. Maximal values of more than 12 ppm CO and more than 2000 ppb NO_x are reached on 18/19 January. The increase of both NO_x and CO at the same time suggests downwelling of air from the upper mesosphere / lower thermosphere as a source. As maximum values of NO_x are reached on January 18/19, their source can therefore not be direct production during the strong geomagnetic storm of January 22, as suggested, e.g., by Renard et al., 2006.”

p10, last paragraph. If photochemical loss of CO moves the NO_x-CO pairs to the left, can't this result in the appearance of points above the secant line? Related to this: What do the vertical "error" bars in Figure 6 denote? Also with regard to Figure 6: The red and orange data (at least; some other points are hidden) have a very peculiar shape – I think the authors should comment on this, if only to ensure that they are not overlooking some important physics that would affect their conclusions.

That is correct – photochemical loss of CO could move the points across the upper secant line as well. The vertical error bars denote the error of the mean of the daily averaged area weighted NO_x values. The peculiar shape in the reds and oranges in the right panel of Figure 6 comes from the development of a NO_x “knee” around mid-February as seen, e.g., in the upper panel of Figure 3 and discussed in the last

C3060

paragraph of page 9; in the CO-versus-NO_x view, this “knee” than shows up as a local NO_x maximum at median CO values. The last paragraph of page 10 has been changed to:

“In the left panel of Fig. 6, the secant to the NO_x-CO relationship is marked as a dashed line. The region comprised by this secant and the NO_x-CO distribution (grey area) can be filled in by mixing processes. Photochemical loss of NO_x would move the NO_x-CO pairs down, while photochemical loss of CO would move NO_x-CO pairs to the left. Values above this region can be gained by direct local production of NO_x, e.g., due to energetic particle precipitation, or by photochemical loss of CO. In the first days after 20 January 2004, the grey mixing region is indeed filled in, while later (mid to late February), the NO_x-CO pairs are moved to the left and downward. This indicates that during the time-interval from 20 January 2004 to 1 March 2004, both mixing processes and photochemical loss of NO_x and CO are important. As discussed before, from mid-February on, a “knee” develops in NO_x due to the different photochemical loss rates of NO_x and CO in the upper stratosphere and lower mesosphere. This is observed as a local NO_x maximum at moderately high CO values in the right panel of Figure 6. Values above the mixing secant are not observed, so there is no evidence for a direct local production of NO_x below 70 km during this time from these observations.”

As suggested by the reviewer, a colorbar for the dates has been added to this Figure, so the red and yellow colors can be easily attributed to mid-February. The error bars are now mentioned in the Figure caption of Figure 6.

p11, lines 19-22. The most significant conclusion from this paper is that the NO_x enhancements observed in the lower mesosphere in Jan-Feb 2004 were not caused by direct production of NO_x, as suggested previously based on an analysis of GOMOS data. This conclusion relies not only on the evidence from MIPAS, but also on the ability of the authors to show that the previously published interpretation of GOMOS data was incorrect. The authors suggest here that had the GOMOS analysis taken into account sampling biases with respect to the "moving wave 2 structure", an NO₂

C3061

enhancement would not have been found. Because contradicting the GOMOS data interpretation is fundamental to their overall point that the enhancements were not caused by direct production (e.g., that the current interpretation of MIPAS data is more correct than the previously published interpretation of GOMOS data), I think the authors should support their speculation more strongly. In particular, they should show that the GOMOS sampling in Jan-Feb 2004 would indeed have led to a bias that would have resulted in a misinterpretation of the data.

We have made a comparison between Mipas footprints and the Gomos data who were used in Clilverd et al., 2009. Night-time ($>106^\circ\text{sza}$) NO₂ mixing ratios at 60km on January 28/29 and at 52 km altitude on February 08/09 and February 14/15 are also compared; a figure will be included in the paper. Gomos data have been provided by Dr. Seppälä who has been added as co-author. Both instruments are qualitatively in very good agreement, showing the same pattern of high/low NO₂ data, but are averaged over different areas of the vortex; even inside the vortex, NO_x is not distributed homogeneously. The text on page 11, line 16 ff is adapted in the following way:

“However, the polar vortex as indicated by high values of both NO_x and CO is elongated at the beginning of this period indicating a wave 2 pattern, which moves and expands to a more circular form from 8 February to 15 February. Because of the wave 2 pattern, the vortex edge is shifted far to the North on February 08/09, and Gomos observations poleward of 70° are taken partly outside the polar vortex (see Figure). Gomos observations both inside and outside the polar vortex agree very well with neighboring Mipas data points, but significantly higher values are also observed by Mipas further in the vortex core. On February 14/15, Gomos observations poleward of 70° are obtained all inside the polar vortex. They are significantly higher than the neighboring Mipas observations, though well within the range of Mipas data elsewhere in the vortex. The reason for the apparent disagreement between daily averages of NO₂ from Mipas and Gomos in this time-period thus appears to be the strongly elongated vortex as well as an inhomogeneous distribution of NO_x inside the vortex. This inhomogeneous distribution is

C3062

already apparent and observed by both instruments in late January, see Figure.”

p12, first paragraph. The authors should be more precise when discussing the problems with analyzing NO_x: What is meant by "cross-talk"?

An explanation of this was added at the end section 2 (MIPAS data):

“NO mixing ratio increases strongly from the lower mesosphere to the lower thermosphere. Thus observations at mesospheric tangent altitudes has a strong thermospheric NO signal in the line-of-sight which might provide an additional positive offset of up to 1.5 ppb, henceforth called “thermospheric cross-talk”. For the retrieval of NO₂ no such information crosstalk happens because the concentration of NO₂ decreases strongly from the upper stratosphere to the thermosphere even during night-time. Thus the measured signal is dominated by radiance emitted near the tangent altitude of each limb observation. Therefore, in the winterhemisphere where NO_x values are in the order of tens of ppb to thousands of ppb, observations of NO_x (NO+NO₂) are used, while in the summer hemisphere, where mixing ratios might be in the range of below 1 ppb, night-time NO₂ and day-time NO are treated separately.”

p13, lines 1-3 (and perhaps on previous page). This refers to NO_x and the lower left panel of Fig. 8, which only shows NO. The text should be clarified.

In the publication mentioned, NO_x is used; in the lower left panel of Figure 8, only daytime NO is shown. This has been clarified in the text as follows: “If the complete polar cap is sampled, enhanced NO_x values decrease more steadily (exponentially) after the solar proton event, as shown, e.g. in Friederich et al. (2013) for NO_x, and in the lower left panel of Fig. 8 for daytime NO.”

p14, lines 13-14. The authors refer to the upper panel of Figure 10, but there is only one row of panels in Figure 10. Since Figure 10 pertains to the same situations as Figure 8, it would be convenient if both figures were formatted the same.

The reference to the upper panel was eliminated, also Figure 10 was formatted as

C3063

suggested.

Finally, I was surprised that several references on the 2003-2004 winter, which I believe are relevant to the current paper, were not cited. I recommend that the authors consider the following papers:

1. Hauchecorne, A., J.-L. Bertaux, F. Dalaudier, J. M. Russell III, M. G. Mlynczak, E. Kyrölä, and D. Fussen (2007), Large increase of NO₂ in the north polar mesosphere in January–February 2004: Evidence of a dynamical origin from GOMOS/ENVISAT and SABER/TIMED data, *Geophys. Res. Lett.*, 34, L03810, doi:10.1029/2006GL027628.
2. Pancheva, D., et al. (2008), Planetary waves in coupling the stratosphere and mesosphere during the major stratospheric warming in 2003/2004, *J. Geophys. Res.*, 113, D12105, doi:10.1029/2007JD009011.
3. Randall, C. E., et al. (2005), Stratospheric effects of energetic particle precipitation in 2003–2004, *Geophys. Res. Lett.*, 32, L05802, doi:10.1029/2004GL022003.
4. Semeniuk, K., J. C. McConnell, and C. H. Jackman (2005), Simulation of the October–November 2003 solar proton events in the CMAM GCM: Comparison with observations, *Geophys. Res. Lett.*, 32, L15S02, doi:10.1029/2005GL022392.
5. Seppälä, A., M. A. Clilverd, and C. J. Rodger (2007), NO_x enhancements in the middle atmosphere during 2003–2004 polar winter: Relative significance of solar proton events and the aurora as a source, *J. Geophys. Res.*, 112, D23303, doi:10.1029/2006JD008326.

Those references will be included.

Minor Technical Corrections

p3, l28. Add "and" before "by Clilverd:" Changed

p5, l25. Add "and" before "about CO:" Changed

C3064

p6, l12. "combining" Changed

p6, l15. "available" instead of "provided" Changed

p6, l22. Remove the comma after "21". Sentence changed

p9, l2. "off in late" not "of in late". Changed

p9, l5. "on the order" not "in the order" [and anywhere else this appears] Changed

p9, l6. "sunlit" (no hyphen) [and anywhere else this appears] Changed here, and in a few other places

p9, l8. "lifetime" and "sunrise " (no hyphens) Changed here, and in a few other places

p9, l25. "development" not "developement" Done

p10, l10. "observed by the MIPAS NOM data". I'm not sure what exactly was meant here, but it can probably be changed to just "observed by MIPAS". Deleted NOM

p10, l19. "seems" rather than "turns" Done

p10, l21. Depending on how you handle the above comment, "NOM" should be defined here. Deleted NOM

p11, l12. "continuously" Done

p11, l20. "stellar" instead of "star" (and no hyphen) Done

p11, l21. Remove "a" before "NO₂" Changed to singular

p12, l14. Add "and" before "NO₂". Done

p14, l24. Either "Exceptions are" or "An exception is" Done

Figure 4 caption. "rate" not "ratef" in the last line Done

Figure 9 caption. "violet" not "violett" Done
