## 9 10 **Abstract**

11 It has been recently reported that the current 2015–2016 El Niño could become “one of the  
12 strongest on record”. To further explore this claim, we performed the new analysis described  
13 in detail in Varotsos et al. (2015) that allows the detection of precursory signals of the strong  
14 El Niño events by using a recently developed non-linear dynamics tool. In this context, the  
15 analysis of the Southern Oscillation Index time series for the period 1876–2015 shows that the  
16 running 2015–2016 El Niño would be rather a “moderate to strong” or even a “strong” event  
17 and not “one of the strongest on record”, as that of 1997–1998.

## 18 19 **1 Introduction**

20 El Niño/La Niña Southern Oscillation (ENSO) is an oceanic-atmospheric quasi-periodic  
21 phenomenon with several impacts on climate and weather not only in the tropical Pacific, but  
22 in many regions all over the world (Varotsos and Deligiorgi, 1991; Kondratyev and Varotsos,  
23 1995a,b; Klein et al., 1999; Xue et al., 2000; Eccles and Tziperman, 2004; Cracknell and  
24 Varotsos, 2007, 2011; Lin, 2007; Chattopadhyay and Chattopadhyay, 2011; Efstathiou et al.,  
25 1998, 2011; Varotsos, 2013; Varotsos et al., 2009a, 2012, 2014a,b). The disastrous effects of  
26 the strong ENSO events necessitate their reliable short and long-term prediction (Latif et al.,  
27 1998; Stenseth et al., 2003; Monks et al., 2009; Hsiang et al., 2011; Cheng et al., 2011;  
28 Barnston et al., 2012; Krapivin and Shutko, 2012; Tippett et al., 2012). In this context,  
29 Varotsos et al. (2015) presented a new method (see also Varotsos and Tzanis, 2012) for the

1 detection of precursory signals of the strong El Niño events by using the entropy change in  
2 “natural time” (a new time domain, see Varotsos et al., 2002) under time reversal. The  
3 analysis of the Southern Oscillation Index (SOI) time series by using this modern method  
4 provided significant precursory signals of two of the strongest El Niño events (1982–1983 and  
5 1997–1998).

6 Very recently, Klein (2015) reported that the running 2015–2016 El Niño could become “one  
7 of the strongest on record”. Furthermore, the Australian Government Bureau of Meteorology  
8 (BOM) in their report  
9 ([http://www.bom.gov.au/climate/enso/archive/ensowrap\\_20150901.pdf](http://www.bom.gov.au/climate/enso/archive/ensowrap_20150901.pdf)) of 1 September 2015  
10 stated that “The 2015 El Niño is now the strongest El Niño since 1997–98” and moreover on  
11 29 September 2015 they reported that most international climate models indicate current El  
12 Niño ([http://www.bom.gov.au/climate/enso/archive/ensowrap\\_20150929.pdf](http://www.bom.gov.au/climate/enso/archive/ensowrap_20150929.pdf)) “is likely to  
13 peak towards the end of 2015” as also reported on 8 October 2015 by the Climate Prediction  
14 Center, National Centers for Environmental Prediction, National Oceanic and Atmospheric  
15 Administration (NOAA)/National Weather Service  
16 ([http://www.cpc.ncep.noaa.gov/products/analysis\\_monitoring/enso\\_disc\\_oct2015/ensodisc.pdf](http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/enso_disc_oct2015/ensodisc.pdf)).  
17 f).

18 In this study, we further explore these claims, by applying to the SOI time series the recently  
19 proposed analysis by Varotsos et al. (2015). The ability of accurate predictions of such severe  
20 natural events, like El Niño, is of crucial importance especially nowadays, where the global  
21 annual average temperature in 2015 reached the warmest on record values, which might be  
22 associated with the 2015 El Niño event (WMO, 2016).

23

## 24 **2 Results and discussion**

25 As mentioned in the previous section, we analyse the SOI time series (Troup, 1965; Power  
26 and Kociuba, 2011) for the period January 1876 – October 2015 by employing the method  
27 described in detail in Varotsos et al. (2015). More specifically, we conduct the analysis of the  
28 SOI monthly values by using the dataset, entitled “Monthly SOI Phase 1887 – 1989 Base”,  
29 (<https://www.longpaddock.qld.gov.au/seasonalclimateoutlook/southernoscillationindex/soidatfiles/index.php>)  
30 derived from the Long Paddock site. It should be clarified that we use the  
31 monthly values of SOI, instead of the daily ones, as the latter introduce significant noise due

1 to daily weather patterns variability. It should be reminded here that El Niño and La Niña  
2 episodes are associated with negative and positive values of the SOI, respectively.

3 The method used by Varotsos et al. (2015) is based on the entropy change in natural time  
4 under time reversal  $\Delta S_i$  (e.g., see Varotsos et al., 2005, 2007, 2009b; Sarlis et al., 2010, 2011)  
5 calculated for a window size of  $i$  events. Within this window, natural time  $\chi_k$  characterizing  
6 the  $k$ -th event is defined by  $\chi_k = k/i$  (Varotsos et al., 2002). The analysis in natural time is  
7 based on the study of the pair  $(\chi_k, Q_k)$  where  $Q_k (> 0)$  is proportional to the “energy” emitted  
8 during the  $k$ -th event. Thus, one can define the quantity  $p_k = Q_k / \sum_{n=1}^i Q_n$  which can be  
9 considered as a probability, since it is positive and satisfies the condition  $\sum_{n=1}^i p_n = 1$   
10 (Varotsos et al., 2011). For the study of El Niño, Varotsos et al. (2015) suggested that  $Q_k$   
11 could be considered proportional to  $(\text{SOI} + c)$ , where  $c$  is an appropriate constant, since  $Q_k$   
12 should be positive. Under these assumptions, the average values of quantities, which are  
13 functions of natural time  $\chi$ , can be evaluated by  $\langle f(\chi) \rangle = \sum_{n=1}^i f(\chi_n) p_n$  and the entropy in  
14 natural time can be defined by  $S = \langle \chi \ln \chi \rangle - \langle \chi \rangle \ln \langle \chi \rangle$  (Varotsos et al., 2005, 2011). The latter  
15 quantity changes to a value  $S_-$  if, instead of the true sequence of events, one uses the time-  
16 reversed process that is described by  $p'_k = \hat{T} p_k = p_{i-k+1}$ , where  $\hat{T}$  denotes the time reversal  
17 operator in the window of  $i$  events. The quantity  $\Delta S_i (= S - S_-)$  reveals the breaking of time-  
18 symmetry by capturing the difference in the dynamics as the system evolves from present to  
19 future and vice-versa. In short, it has been shown (e.g., see Varotsos et al., 2007, 2011) that  
20 positive values of  $\Delta S_i$  correspond to a decreasing time-series in natural time, and hence when  
21  $\Delta S_i$  exceeds a certain threshold this reveals that SOI is approaching at small values indicating  
22 El Niño (Varotsos et al., 2015). Varotsos et al. (2015) have also shown (see their Fig. 4) that  
23 the most useful window size for this purpose is  $i = 20$  events (months). In their prediction  
24 scheme, the monthly SOI values for the past 20 months are used for the calculation of  $\Delta S_{20}$   
25 (see the red crosses in Figs. 1 and 3) and compared with a threshold  $\Delta S_{\text{thres}}$ , which can be  
26 determined on the basis of Receiver Operating Characteristics (ROC, see Fawcett, 2006).  
27 ROC is a method for the visualization, evaluation, and selection of prediction schemes based  
28 on their performance, which is quantified by a plot of the hit rate vs. the false alarm rate  
29 obtained by the following procedure applied to the present case. When  $\Delta S_{20} \geq \Delta S_{\text{thres}}$ , one

1 issues an alarm that the value of SOI for the next month will be smaller than or equal to  $T$  (see  
2 the black broken line in Fig. 2). If this turns out to be true, then we have a true positive  
3 prediction. If  $\Delta S_{20} < \Delta S_{\text{thres}}$  and the next month's SOI is larger than  $T$ , then we have a true  
4 negative prediction. All other combinations lead to errors (which are inevitable in stochastic  
5 prediction), which can be either false positive or false negative predictions. Figure 2 depicts  
6 the ROC curve obtained, when using  $\Delta S_{20}$  as a predictor for the SOI value of the next month  
7 with  $T = -14$  (which is the upper limit of the yellow area in Figs. 1 and 3 discussed below).  
8 This is a diagram of the hit rate (or True Positive rate, i.e., the number of true positive  
9 predictions over all cases with  $\text{SOI} \leq T = -14$ ) vs. the false alarm rate (or False Positive rate,  
10 i.e., the number of false positive predictions over all cases with  $\text{SOI} > -14$ ) as we vary  $\Delta S_{\text{thres}}$ .  
11 A method to estimate an appropriate value of  $\Delta S_{\text{thres}}$  is that of iso-performance lines suggested  
12 by Provost and Fawcett (1998, 2001). In this scheme, a line of constant slope  $m$  (see the blue  
13 line in Fig. 2) is selected on the basis of the relative cost of false positive predictions over the  
14 cost of false negative predictions multiplied by the relative frequency of negatives over  
15 positives, i.e., see Eq. (1) of Fawcett (2006). As a typical selection we chose  $m = 1$ . We fitted  
16 ROC points with the red curve (having a simple analytical form  $a + b\sqrt{x} + cx^d$ ) and  
17 determined the point at which the slope was unity. This leads to the ROC point indicated by  
18 an arrow in Fig. 2 and corresponds to  $\Delta S_{\text{thres}} = 0.0035$  (i.e., a value very close to that 0.00326  
19 presented in Table 1 of Varotsos et al (2015) for  $T = -15$ ). Thus, in Figs. 1 and 3 when  $\Delta S_{20} \geq$   
20 0.0035 the alarm is set on for the SOI value of the next month.

21 The time progress of the SOI monthly values as well as the entropy change in natural time  
22 under time reversal (for the window length  $i = 20$  months)  $\Delta S_{20}$  are depicted in Fig. 1 (as well  
23 as in Fig. 3). Beyond the information gained from the exploration of the  $\Delta S_{20}$  dynamics and in  
24 order to further identify if 2015–2016 El Niño could be characterized as a “very strong” one  
25 or even more as “one of the strongest on record”, we followed the classification and  
26 characterization of the past El Niño events given by BOM  
27 (<http://www.bom.gov.au/climate/enso/enlist/>). The coloured areas in Figs. 1 and 3 represent  
28 the mean minimum negative values of SOI along with the  $1\sigma$  standard deviation bands for the  
29 two cases of “weak, weak to moderate, moderate, moderate to strong” (green band) and  
30 “strong, very strong” (yellow band) El Niño events.

31 As can be clearly seen in Fig. 3, the SOI values during the last three months remain in the  
32 green band and in the limits of the yellow one, indicating that 2015 El Niño should be rather

1 characterized as a “moderate to strong” or even “strong” event and not “one of the strongest  
2 on record”, as also shown by comparing with the El Niño events of 1982–1983 and 1997–  
3 1998. Furthermore, the variation of  $\Delta S_{20}$  during the 2015 El Niño in comparison with 1982–  
4 1983 and 1997–1998 El Niño events is not as sharp, confirming that the undergoing El Niño  
5 event is not “one of the strongest on record”. In order to estimate the extent of this variation,  
6 we plot with the black curve in Fig. 4 the probability density function (PDF) of  $\Delta S_{20}$  obtained  
7 from the estimator  $f_N(\Delta S_{20}) = \frac{1}{N} \sum_{i=1}^N \frac{1}{b_N} K\left(\frac{\Delta S_{20} - O_i}{b_N}\right)$ , where  $O_i$  are the observed values of  
8  $\Delta S_{20}$  since the beginning of our study,  $N$  is the total number of these observations, the kernel  
9  $K(x)$  is non-zero only when  $|x| < 1$  having the value  $K(x) = \frac{3}{4}(1 - x^2)$  and  $b_N$  is related with the  
10 standard deviation  $\sigma$  of the observed  $\Delta S_{20}$  values by  $b_N = 10.25\sigma/N^{0.34}$  as suggested by  
11 Mercik et al. (1999). We observe in Fig. 4 that only rarely  $\Delta S_{20}$  exceeds the value of 0.02,  
12 which can be also verified by the red histogram obtained for  $\Delta S_{20}$  using the TISEAN package  
13 (Hegger et al., 1999) (also plotted in Fig. 4). In the latter histogram, the minimum non-zero  
14 height is observed in the bar that includes the value  $\Delta S_{20} = 0.02$  covering the range up to  
15 approximately 0.0205. To detect when  $\Delta S_{20}$  exceeds the latter value, we plot with blue crosses  
16 the time series of  $\Delta S_{20}$  vs. time, which can be read in the right axis of Fig. 4. We see (blue  
17 arrows in Fig. 4) that  $\Delta S_{20} > 0.0205$  is observed only in the three strong El Niño events of  
18 1905-1906, 1982-1983 and 1997-1998. This inequality, however, is not fulfilled in the current  
19 case (2015–2016 El Niño), since the currently observed values are close to 0.01, i.e.,  
20 markedly smaller than the value of 0.0205.

21

### 22 **3 Conclusions**

23 Recent reports indicate that 2015–2016 El Niño event could become “one of the strongest on  
24 record” or could be already characterized as “the strongest El Niño since 1997–98”. In order  
25 to investigate these assertions, we analyzed the SOI time series for the period January 1876 –  
26 October 2015 by using the method described in Varotsos et al. (2015) based on the entropy  
27 change in natural time under time reversal. The results obtained indicate that the undergoing  
28 2015–2016 El Niño event should be rather characterized as a “moderate to strong” or even  
29 “strong” event and not “one of the strongest on record”.

3 **Figure 1.** The entropy change  $\Delta S_{20}$  in natural time for the window length  $i = 20$  months (red  
4 line, left scale) along with SOI monthly values (blue line, right scale) for the period January  
5 1980 – October 2015. The alarm is set on (black line), when  $\Delta S_{20}$  exceeds the threshold value  
6  $\Delta S_{\text{thres}} = 0.0035$ .

7

8 **Figure 2.** The hit rate vs. false alarm rate when using  $\Delta S_{20}$  as a predictor for the SOI value of  
9 the next month. The ROC point indicated by the arrow has been selected so that the slope of  
10 the tangent of the analytical fitting of the ROC points indicated by the red curve has unit slope  
11 and hence it corresponds to the  $m = 1$  iso-performance line of the ROC space (e.g., see  
12 Fawcett, 2006; Provost and Fawcett, 1998, 2001).

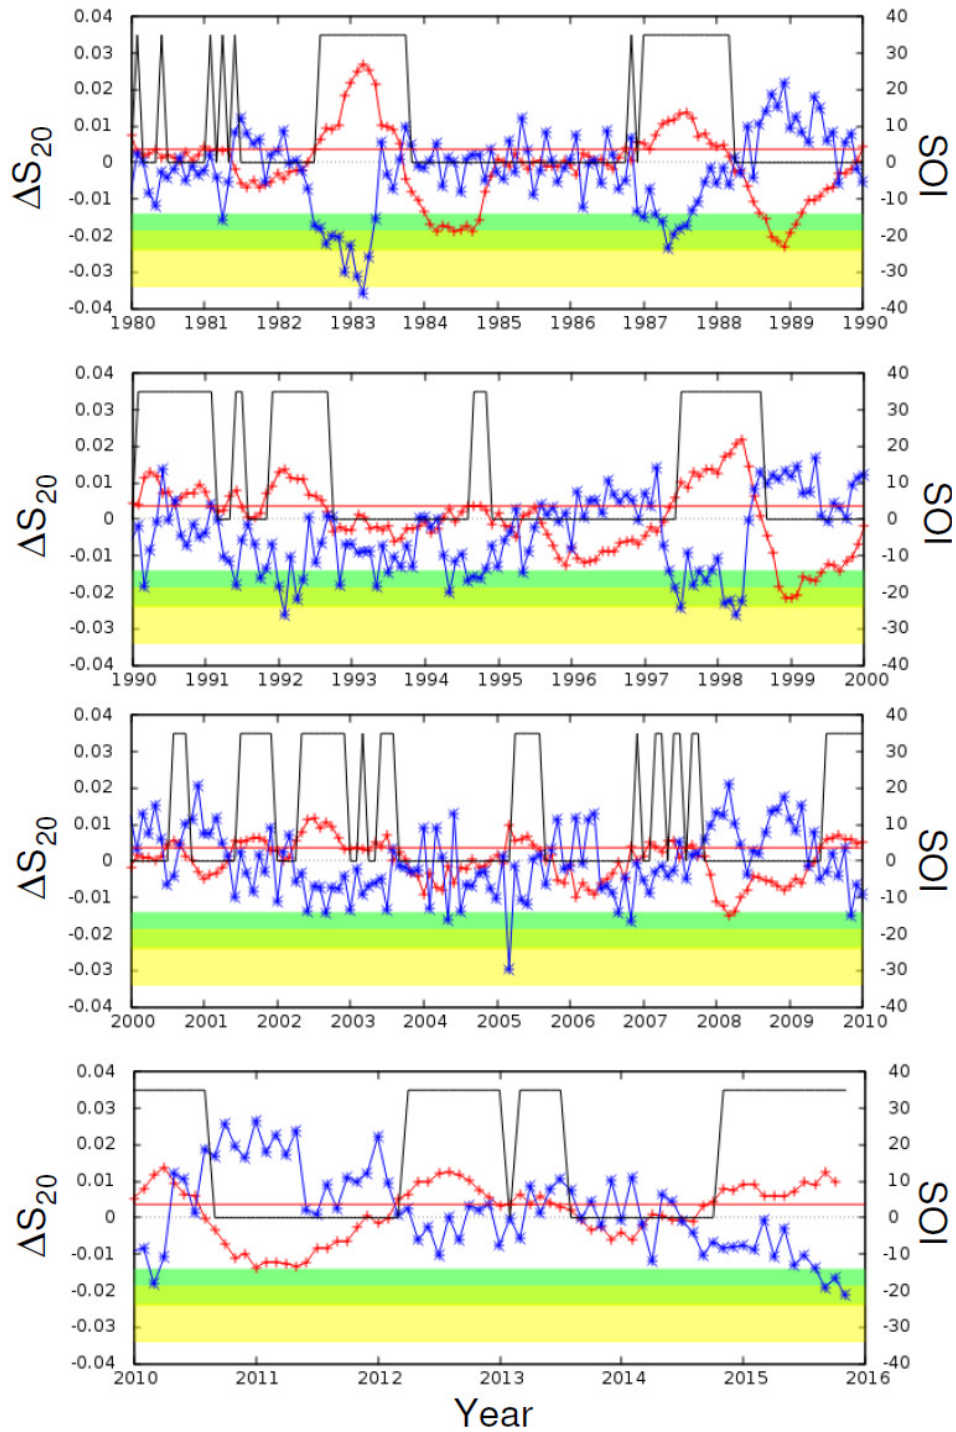

13

14 **Figure 3.** As in Fig. 1, but only for the 1982–1983, 1997–1998 (the two strongest in the last  
15 century) and the current 2015–2016 El Niño events.

16

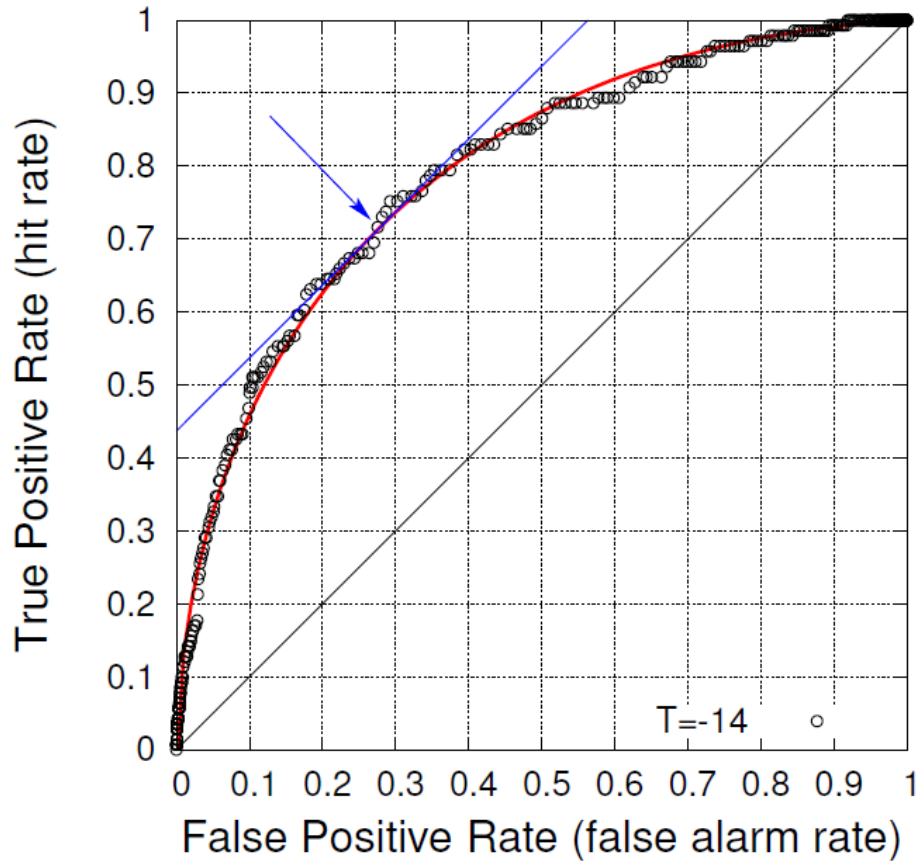

17 **Figure 4.** The PDF of  $\Delta S_{20}$  (black curve, left scale) together with the corresponding histogram  
18 (red bars, left scale) obtained from the time series of  $\Delta S_{20}$ , which is also plotted vs. time (blue  
19 crosses, right scale) along the vertical axis. The arrows indicate when  $\Delta S_{20}$  exceeds 0.0205  
20 and are labeled by the corresponding ongoing strong El Niño events.
