

Interactive comment on “The importance of interstitial particle scavenging by cloud droplets in shaping the remote aerosol size distribution and global aerosol-climate effects” by J. R. Pierce et al.

Anonymous Referee #2

Received and published: 29 April 2015

This paper explores the role of coagulation of interstitial aerosol particles with cloud droplets. The authors find that this process reduces cloud condensation nuclei concentrations by 10% with a non-negligible impact on cloud albedo. The paper argues that this process should be included in aerosol – climate models. The paper will be of interest to the aerosol modelling and aerosol – climate communities. The paper is well written and I suggest publication in ACP. A few minor editorial corrections are listed below.

It would be interesting to see how this process alters the simulated aerosol size distribution – this would also help interpret the reported changes to aerosol number con-

centrations. A suggestion would be to plot simulated aerosol size distributions from the BASE simulation in comparison to one of the other simulations at a few locations.

Minor corrections
