

## ***Interactive comment on “Measurements of N<sub>2</sub>O<sub>5</sub>, NO<sub>2</sub>, and O<sub>3</sub> east of the San Francisco Bay” by E. C. Wood et al.***

**E. C. Wood et al.**

Received and published: 12 January 2005

We thank Referee #1 for the comments.

1. The authors should note that one reason for the dominance of the nighttime pathway is the small calculated OH concentration. In fact, the rate of both day and night loss processes for NO<sub>x</sub> are considerably smaller under these conditions than in summer. A quick estimate and contrast of the NO<sub>x</sub> lifetime in summer and winter would be an interesting addition to this discussion.

---

We have added text in the discussion of our revision contrasting the NO<sub>x</sub> losses in summer and winter, noting both that OH changes and that the chemistry

of the nocturnal and residual layer is therefore quite different in the two seasons.

---

2. The interpretation of the signal, which is the sum of  $\text{NO}_3$  and  $\text{N}_2\text{O}_5$ , exclusively as  $\text{N}_2\text{O}_5$  is reasonable under the conditions described. The authors should perhaps note more explicitly that the correction for the  $\text{NO}_3$  contribution would range from roughly 1 - 10% for the stated range of conditions.

---

We have added a statement to this effect in the text of the revision.

---

3. The height of the inlet above the ground surface was 1.2 m. Is it possible that deposition to the ground plays a role in the  $\text{N}_2\text{O}_5$  loss? If so, the lifetime of  $\text{N}_2\text{O}_5$  with respect to hydrolysis on aerosol may not be as short as inferred. Previous modeling studies of Geyer, Stutz and coworkers have showed that there may be significant vertical gradients in  $\text{NO}_3$  and  $\text{N}_2\text{O}_5$ , especially within the last few meters above the ground surface.

---

We have added text in the revision discussing vertical gradients describing possible effects of deposition and emissions of  $\text{NO}$ . Geyer and Stutz, who highlight the effects of  $\text{NO}$ , were making observations directly in a source region. Their model is one-dimensional and assumes uniform  $\text{NO}$  emissions at the bottom. Our situation is slightly different in that we expect zero  $\text{NO}$  emissions in the near field because we are several km from the source region.

---

4. Figure 3: Why is the  $\text{NO}_2$  concentration only displayed when there is  $\text{N}_2\text{O}_5$  present? Is there a more complete time series in  $\text{NO}_2$ , or was the  $\text{NO}_2$  instrument only running simultaneously with the  $\text{N}_2\text{O}_5$  measurement?

---

There are NO<sub>2</sub> measurements shown when N<sub>2</sub>O<sub>5</sub> was not present. Although power to the instruments failed on January 5th, the NO<sub>2</sub> instrument was running continuously on January 6th. We added text in the revision to highlight those measurements.

---

Technical comments: 1. Page 8: At low NO and NO<sub>3</sub> concentrations, the quantity  $F(\text{NOSUM}) = 2[\text{N}_2\text{O}_5]/(2[\text{N}_2\text{O}_5] + [\text{NO}_2])$  rather than  $2[\text{N}_2\text{O}_5]/[\text{NO}_2]$ .

---

This has been changed in the revision as suggested.
