Correspondence to: A. Baklanov (alb@dmi.dk)

**Abstract**

The quality of the urban air pollution forecast critically depends on the mapping of emissions, the urban air pollution models, and the meteorological data. The quality of the meteorological data should be largely enhanced by using downscaled data from advanced numerical weather prediction models. These different topics, as well as the application of population exposure models, have traditionally been treated in distinct scientific communities whose expertise needs to be combined to enhance the possibilities of forecasting air pollution episodes in European cities. For this purpose the EU project "Integrated Systems for Forecasting Urban Meteorology, Air Pollution and Population Exposure" (FUMAPEX) ([http://fumapex.dmi.dk](http://fumapex.dmi.dk)), involving 22 organizations from 10 European countries, was initiated. The main objectives of the project are the improvement of meteorological forecasts for urban areas, the connection of numerical weather prediction models to urban air pollution and population exposure models, the building of improved Urban Air Quality Information and Forecasting Systems, and their application in cities in various European climates. This paper overviews the project items and first two-years results, it is an introduction to the whole ACP issue.

## 1. Introduction

The last decades have seen a general improvement of the air quality within many of the European urban areas. The use of cleaner fuel and improved technologies for private heating, the introduction of catalytic devices in new generation cars, and the contextual decommissioning of industrial activities have all contributed to the lowering of urban air concentrations of primary pollutants ($SO_2$, $NO_x$, PM, etc.) in most populated EU cities. Nevertheless, urban air quality (UAQ) is still considered as a problem especially during short-term episodes that occur during adverse meteorological conditions, causing exceedances of short-term air quality standards (e.g. during episodes in 1995 in London $NO_2$ exceeded 400 ppb). Short-term pollution episodes are presently one of

EGU

the major concerns for the protection of human health in urban environment. This has lead to the introduction of EU Air Quality Directives to abate adverse health effects of air pollution to European citizens. The new EU air quality standards to be implemented by 2005 and 2010 will focus even more on episode prevention and forecasting. More-
over, a reliable urban scale forecast of air flows and meteorological fields is of primary support for urban emergency management systems for accidental toxic releases, fires, or even chemical, radioactive, or biological substance releases due to terrorist actions, the potential risk of which has been recently emerged.

The quality of the urban air pollution forecast and the Urban Air Quality Information and Forecasting Systems (UAQIFS) critically depends on the: (i) mapping of emissions, (ii) level of urban air pollution (UAP) models, and (iii) quality of meteorological fields in urban areas. The main problem in forecasting of UAP is the prediction of episodes with high pollutant concentration in urban areas. In these areas most of the well-known methods and models, based on in-situ meteorological measurements, fail to produce realistically the meteorological input fields for the UAP models. Many projects are aimed at developing UAP dispersion models and chemical transformation and at improving knowledge about pollutants and emissions. However, no significant efforts were put to improving forecasts of meteorological parameters in UAP models. These would be especially important in air pollution episodes (APEs) with low winds, stable stratification, local air circulations, topographic effects, breeze conditions, and internal boundary layers.

Historically, UAP forecasting and numerical weather prediction (NWP) were developed separately. This was plausible in the previous decades when the resolution of NWP models was too low for city-scale air pollution forecasting. However, during the last decade substantial progress in NWP modelling and in the description of urban atmospheric processes was achieved. Modern nested NWP models utilise land-use databases down to hundred meters resolution or finer, and approach the necessary horizontal and vertical resolution to provide weather forecasts for the urban scale (see e.g. Baklanov et al., 2002). In combination with the recent scientific developments in

EGU

the field of urban sublayer atmospheric physics (e.g. Martilli et al., 2002; Dupond et al., 2005a, b; Fisher et al., 2005) and the enhanced availability of high-resolution urban surface characteristics, the capability of NWP models to provide high quality urban meteorological data will, therefore, increase.

5  UAP models in operational UAQIFSs, as a rule, still use simple in-situ meteorological measurements which are fed into meteorological pre-processors (see Fig. 1 in Baklanov et al., 2005a). Lacking an adequate description of physical phenomena and the complex data assimilation and parameterisations of NWP models, these pre-processors do not achieve the potential of NWP models in providing all the meteoro-
10  logical fields needed by modern UAP models to improve the UAQ forecasts.

Despite the increased resolution of existing operational NWP models, urban and non-urban areas mostly contain similar sub-surface, surface, and boundary layer formulation. These do not account for specifically urban dynamics and energetics and their impact on the numerical simulation of the atmospheric boundary layer and its
15  various characteristics (e.g. internal boundary layers, urban heat island, precipitation patterns). Additionally, NWP models are not primarily developed for air pollution modelling and their results need to be designed as input to urban and mesoscale air quality models.

Existing large scale pollution forecasting systems are already operating over do-
20  mains that cover the European continent. Even if these systems do not have a spacial resolution sufficient to resolve the urban structure and meteorology, they provide the background to estimate boundary conditions and to evaluate the importance of large scale flow of pollutants over the target cities.

Urban populations spend typically over 80% of their time indoors at geographically
25  varying locations during the day. The pollution they inhale indoors is filtered by the buildings and the ventilation systems. During the last decades increasing attention has been paid to these factors modifying the true exposure levels the populations experience. The ambient air quality, measured and modelled, is important for the ambient air quality management, but when the adverse health effects of the population are as-

EGU

sessed, the time activity of population must be taken into account.

Therefore, due to the above mentioned reasons, the situation in UAQIFS is changing nowadays and requires a revision of the conventional conception of UAQ forecasting.

## 2. Project objectives and realisation

In response to the above mentioned research needs, the European Union research project called FUMAPEX: "Integrated Systems for Forecasting Urban Meteorology, Air Pollution and Population Exposure" was initiated within the COST 715 community (Fisher et al., 2005), and submitted to the Fifth Framework Programme, Subprogramme: Environment and Sustainable Development, Key Action 4: City of Tomorrow and Cultural Heritage. FUMAPEX started in November 2002 and will continue for a period of three years. FUMAPEX is a member of the CLEAR cluster of European Urban Air Quality Research (http://www.nilu.no/clear).

The main objectives of the FUMAPEX project are the following: (i) to improve meteorological forecasts for urban areas, (ii) to connect NWP models to UAP and population exposure (PE) models, (iii) to build improved UAQIFS, and (iv) to demonstrate their application in target cities located in various European climates. The FUMAPEX scheme of the improvements of meteorological forecasts in urban areas, interfaces and integration with UAP and PE models for the UAQIFS is presented in Fig. 1 of Baklanov et al. (2005b)[1].

The improvement of urban meteorological forecasts will also provide information to city management regarding additional hazardous or stressing urban climate (e.g. urban runoff and flooding, icing and snow accumulation, high urban winds or gusts, heat or cold stress in growing cities and/or a warming climate). Moreover, the availability of

Interactive Discussion

EGU

reliable urban scale weather forecasts could be of relevant support for the emergency management of fires, accidental toxic emissions, potential terrorist actions, etc. (Baklanov et al., 2006).

The improved forecast techniques can be used in two ways. Firstly, it can be the short-term episode forecasts for the next few days. Secondly, it is an integrated modelling system for long-term air quality management to predict future episodic pollution levels, taking into account estimated trends in local traffic and other emissions. In both ways the modelling system can be employed to evaluate alternative scenarios and to develop efficient strategies to reduce emissions, pollution levels, and PE to prevent health consequences in a cost-effective way.

In order to achieve the innovative project goal of establishing and implementing the improved UAQIFS to assist sustainable urban development, the following steps should be achieved:

1. improve predictions of the meteorological fields needed by UAP models by refining resolution and developing specific parameterisations of the urban effects in NWP models,

2. develop suitable interface/meteorological pre-processors from NWP to UAP models,

3. validate the improvements in NWP models and meteorological pre-processors by evaluating their effects on UAP models against urban measurement data,

4. apply the improved meteorological data to UAQIFS, emergency preparedness and PE models, compare and analyse results, and

5. successfully link meteorologists/NWP modellers with UAP and public health scientists and 'end-users' of UAQIFS.

The necessary steps are evolved in 10 separate, but inter-linked Work Packages (WP, see below and Fig. 1) realised by 16 partners and 6 subcontractors (see the list of the

participants in Table 1). They represent leading NWP centres, research institutions, organisations responsible for UAQ, PE forecast and control, and local/city authorities from 10 European countries.

The WP structure (with leaders) is the following:

WP 1: Analysis and evaluation of APEs in European cities (J. Kukkonen, FMI)

WP 2: Assessment of different existing approaches to forecast UAP episodes (R. S. Sokhi, UH)

WP 3: Testing the quality of different operational meteorological forecasting systems for urban areas (B. Fay, DWD)

WP 4: Improvement of parameterisation of urban atmospheric processes and urban physiographic data classification (A. Baklanov, DMI)

WP 5: Development of interface between urban-scale NWP and UAP models (S. Finardi, Arianet)

WP 6: Evaluation of the suggested system (UAQIFS) to uncertainties of input data for UAP episodes (N. Bjergene, DNMI)

WP 7: Development and evaluation of PE models in combination with UAQIFS's (M. Jantunen, KTL)

WP 8: Implementation and demonstration of improved UAQIFS (L. H. Slørdal, NILU)

WP 9: Providing and dissemination of relevant information (A. Skouloudis, JRC)

WP 10: Project management and quality assurance (A. Rasmussen, DMI).

## 2.1. Project realisation

The project proceeds through the steps given below, each of which can be considered as a separate objective providing valuable results:

1. Classification of APEs in cities located in different European climatic and geographic regions (Fig. 2) focusing on relevant meteorological variables.

– Identification and classification of various types of APEs.

– Key pollutants relevant to EU Air Quality Directives and Daughter Directives

**FUMAPEX overview**

A. Baklanov

EGU

(EC/96/62; EC/99/30) will be selected for different regions/city characteristics.

- – Classification of meteorological conditions leading to pollution episodes and identification of the more relevant meteorological parameters to define these conditions.
- – Compilation and analysis of existing datasets of concentration and meteorological data measured during pollution episodes.

2. Improvement of the quality of urban meteorological forecasting for UAP and PE models

- – Improvement of urban weather forecasts and calculation of key meteorological parameters for pollution episodes (a hierarchy of NWP models from large scale Global Circulation Models to local-scale obstacle-resolving meteorological models will be employed).
- – Improvement of boundary layer formulations/parameterisations and physiographic data description for urban areas.
- – Development of assimilation techniques with satellite remote sensing data in NWP models.
- – Development of interfaces to connect urban-scale NWP to UAP models.

3. Verification of the improved NWP, UAP, and PE models

- – Evaluation of improved urban meteorological forecast models based on UAP episode.
- – Estimation of sensitivity of UAP models to uncertainties in meteorological input data.
- – Evaluation of impact of the improved output of UAQ models on simulations of an urban PE model.

**FUMAPEX overview**

A. Baklanov

EGU

4. Application of UAQIFS and emergency systems.

– Integration of the improved NWP, UAP and PE models into UAQIFSs.

– Implementation of the new improved UAQIFS in the (i) air quality forecasting mode to be applied in four target cities, (ii) urban management or public health and planning mode in one selected target city, and (iii) the improved emergency preparedness system in one selected target city.

The six target city candidates for the improved UAQIFS and emergency systems implementations and corresponding 'end-users' are the following (Fig. 2):

| | |
|---|---|
| #1 – Oslo (Norway) | ⇒ Municipality of Oslo, Norwegian Traffic Authorities; |
| #2 – Turin (Italy) | ⇒ Environmental Protection Agency of Piedmont; |
| #3 – Helsinki (Finland) | ⇒ Helsinki Metropolitan Area Council; |
| #4 – Castellon/Valencia (Spain) | ⇒ Centro De Estudios Ambientales Del Mediterrano; |
| #5 – Bologna (Italy) | ⇒ Environmental Protection Agency of Emilia-Romagna; |
| #6 – Copenhagen (Denmark) | ⇒ Danish Emergency Management Agency. |

## 3. Project scientific achievements

In order to resolve the above-discussed issues and FUMAPEX objectives, at the current stage of the project (after the first two years) the following innovative studies were realised for UAQIFSs:

• The database of meteorological and chemical measurement data for UAP episodes in European cities was established and key meteorological parameters for those episodes/climatological regions identified and classified (Valkama et al., 2004; Kukkonen et al., 2005). These can also serve for future NWP/UAP model development and validation.

• The assessment and intercomparison of the present simple and complex meteorological pre-processors to UAP models was provided (Slördal et al., 2005; Sokhi

et al., 2003; Batchvarova et al., 2003). The attention was focused on characterisation of the urban boundary layer and to aspects more relevant to the 'end-users' needs.

- Project leads to the investigation and improvement of different European operational NWP models in urban environment and a validation of these modified models on urban measurements for selected European cities and typical high pollution episodes (Baklanov et al., 2005a). The study of performance of NWP models with higher resolution was performed for urban areas (Fay et al., 2005; Neunhäuserer et al., 2004).

- Three variants of the NWP model 'urbanisation' were suggested; improved parameterisations of the urban boundary layer in NWP models were established and validated (Baklanov et al., 2005a; Hamdi and Shayes, 2005), consisting of improved urban temperature and heat flux parameterisations and their effects on winds, turbulence, stability, and mixing height.

- The important urban soil and surface parameterisations (Mestayer and Bottema, 2002) improved by providing and validating state-of-the-art soil and roughness models for urban areas (Dupont et al., 2005[2]; Martilli et al., 2002; Baklanov et al., 2005a; Mahura et al., 2005) and scale-dependent input parameters for the obstacle resolving UAPs were realised due to the new European regulations.

- Improved theory and parameterisation of turbulence and mixing height, with a focus on the relevant stable boundary layer, are suggested and tested for urban NWP/UAP models (Zilitinkevich et al., 2002, 2005; Zilitinkevich and Baklanov, 2002; Zilitinkevich and Esau, 2004; Baklanov, 2002; Finardi et al., 2005).

- The extended data assimilation of surface characteristics into the urban scale NWP models can add crucial data and, thus, improve the models. High resolution

EGU

EGU

satellite data (e.g. remotely sensed snow cover and heat fluxes in urban areas) were accommodated, and assimilation algorithms were developed and tested for urban areas (Kitwiroon et al., 2002; Eastwood et al., 2004).

- Project also provided improved model interfaces/meteorological pre-processors, capable of connecting mesoscale meteorological model results to updated UAP and atmospheric chemistry models, which incorporated the above improvements in resolution, data assimilation, and parameterisation (Finardi et al., 2005).

- The sensitivity study on the relevance of the above modifications in NWP models and meteorological pre-processors on the detailed description of local circulation and urban meteorology was established and validated with meteorological measurements for APEs in European cities (Fay et al., 2005; Baklanov et al., 2005a; Neunhäuserer and Fay, 2005).

- The sensitivity study on the relevance of the above modifications on the performance of UAP models in UAQIFS was realised and validated with measurements of APEs in European cities (Ødegaard et al., 2005; Palau et al., 2005).

- Improved urban meteorology and air pollution modelling systems suitable to be applied to any European urban area on the basis of available operational NWP models were established (Slördal, 2004). These new UAQIFSs are implementing in 6 selected European target cities and demonstrating with the direct participation of local authorities and other 'end-users'.

- Linking ambient air pollution models with population time-activity to assess the true exposure levels caused by the ambient pollution was realised (Hänninen, 2005; Jantunen et al., 2004, 2005) and the new generation UAQIFS, integrated from urban meteorology to air quality and population exposure, was built and tested for some target cities, e.g. Helsinki (Jantunen et al., 2004, 2005; Hänninen et al., 2005a, b; Baklanov et al., 2005b[1]).

Some of the above mentioned results and achievements of the FUMAPEX project are presented in papers of this special issue, other are published in different papers and reports shown in Sect. 4.

## 3.1. Project expected impacts

The main impact of the FUMAPEX project will be the improved, validated, inter-compared, and accessible UAQIFS implemented in an increasing number of European cities. Forecast and prevention of the worst air pollution episodes in large cities according to air quality directives will lead to an improved quality of human life and environment.

Additional impacts are the potential use of improved weather and pollution forecasts for emergency management (fires, accidental emissions, terror actions, etc.) and for long-term air quality management (scenario studies, emission abatement strategies, sustainable city life, etc.). Linking scientists and administrators of different background, disciplines, and specialisation will also lead to speeding-up and innovation in related urban research and application (e.g. urban climate, sustainable transport, environment, health, etc.) addressed by the EC framework program.

## 4. FUMAPEX publications

The complete list of FUMAPEX publications (including conference proceedings and presentations) as well as the below mentioned reports are available on the project web-site: http://fumapex.dmi.dk.
