

## ***Interactive comment on “Night-time radical chemistry during the NAMBLEX campaign” by R. Sommariva et al.***

### **Anonymous Referee #1**

Received and published: 26 September 2006

General comments: Sommariva et al. investigate the nighttime chemistry of OH/HO<sub>2</sub>/RO<sub>2</sub>/NO<sub>3</sub> radicals during the NAMBLEX campaign. Their analysis included comparisons between the observed and modeled radical concentrations and radical flux analyses in the model. Nighttime OH/HO<sub>2</sub>/RO<sub>2</sub> chemistry and NO<sub>3</sub> chemistry have been studied in various environments, but often they have been separately investigated because simultaneous measurements of all the radicals have been achieved rarely. It is new that the authors provide analysis with emphasis of the connections between the HO<sub>x</sub> and NO<sub>3</sub> cycles, making full use of broad observations during the campaign. My major concern is that it is difficult to find out what is the original analysis of this paper in this special issue with many related papers (e.g. Smith et al. 2006, Fleming et al. 2006, Bitter et al. in preparation), which include nighttime analysis of

the radicals at least as their parts. This point needs clarification. Overall, this study is within the scope of Atmospheric Chemistry and Physics. I suggest that the paper should be published after taking into account the following minor comments.

Specific comments:

1. page 7717 last line: “especially”

2. page 7719, line 15. It is mentioned that the NMHCs data were linearly interpolated to 15 min. The original frequency of the NMHC measurements (40 min? from Heard et al. (2006)) should be included here.

3. page 7720, lines 10-19. It is not clear whether the observed boundary layer height is used in the model to calculate deposition rates.

4. page 7721, lines 2-4, 6, 11, and 15. Integration time and signal-to-noise ratio with which the detection limits of OH, HO<sub>2</sub>, HO<sub>2</sub>+RO<sub>2</sub>, and NO<sub>3</sub> are calculated should be given.

5. In section 2, the times of sunset and sunrise should be specified for the campaign period to define nighttime.

6. page 7722, line 5. Nighttime OH was below the detection limit ( $6 \times 10^{-4}$  molecule cm<sup>-3</sup>). It seems from the inset graph of Figure 1a that modeled OH (full-oh) sometimes reaches  $1 \times 10^{-5}$  molecule cm<sup>-3</sup>. Does this suggest model's overprediction of OH? Can the authors discuss nighttime OH levels with averaging intervals longer than 15 min?

7. page 7722, lines 9-10. The presence of an OH source unaccounted for or underestimated by the model “at sunrise”, such as HONO. How do the authors explain the model's overestimation at sunset?

8. page 7722, line 17. Is the uncertainty of the model calculated for the nighttime of the NAMBLEX campaign?

9. page 7722, lines 26-28. Fleming et al. (2006) suggests that the peroxy radical in-

crease with NO<sub>x</sub> is suggestive of NO<sub>3</sub> reacting with hydrocarbons to form peroxy radical. However, this study shows that the increase in [HO<sub>2</sub>+RO<sub>2</sub>] with NO<sub>x</sub> increase is not reproduced by the model including NO<sub>3</sub> chemistry. Are the model results completely different if constrained by observed NO<sub>3</sub>? Or is this positive correlation between NO<sub>x</sub> and HO<sub>2</sub>+RO<sub>2</sub> attributable to unknown production of HO<sub>2</sub>+RO<sub>2</sub> rather than NO<sub>3</sub> chemistry? In Figure 1a and 1b, both observed HO<sub>2</sub> and HO<sub>2</sub>+RO<sub>2</sub> show peaks at around 22:00 - 23:00 when NO<sub>2</sub> shows a maximum (Figure 7), while the modeled HO<sub>2</sub> and HO<sub>2</sub>+RO<sub>2</sub> do not show any peaks. These features could also suggest unknown production of HO<sub>2</sub> or HO<sub>2</sub>+RO<sub>2</sub>.

10.page 7724, line 17. In Figure 3a, modeled NO<sub>3</sub> is not shown. Only modeled NO<sub>3</sub>+N<sub>2</sub>O<sub>5</sub> is compared to the measurement by CRDS.

11.page 7724, lines 20-22. How large is the uncertainty in the CRDS measurements of NO<sub>3</sub>? Can it be included in Figure 3a as error bars?

12.page 7725, line 17. Only effect on modeled [NO<sub>3</sub>+N<sub>2</sub>O<sub>5</sub>] (not [NO<sub>3</sub>]) can be seen in Figure 3a. Is heterogeneous loss of N<sub>2</sub>O<sub>5</sub> with  $\gamma = 0.016 - 0.032$  slower than its gaseous reactions with H<sub>2</sub>O assumed in the model?

13.page 7726, line 2. Regina et al., 1998

14.page 7726. In addition to NO and DMS, can I<sub>2</sub>, measured up to 90 pptv in nighttime during the campaign, provide significant sink of NO<sub>3</sub> by the reaction between them with a rate coefficient of  $1.5 \times 10^{-12} \text{ cm}^3 \text{ molec}^{-1} \text{ s}^{-1}$  (Chambers et al. 1992)?

15.page 7726, last paragraph. Can a vertical gradient of NO, which is possibly present when considering its emission from soil, also affect the vertical NO<sub>3</sub> gradient?

16.page 7727, line 25 and Figure 5. Are the two reactions OH + O<sub>3</sub> and OH + H<sub>2</sub> shown together in a single series in Figure 5?

17.page 7728, line 5. The authors mention that propene, c-2-butene, t-2-butene, c-2-pentene, and t-2-pentene are important to produce radicals from O<sub>3</sub> + alkene reac-

tions. In addition to propene concentrations specified in Table 2, the levels of the other alkene concentrations should be listed. The radical production rate from ozonolysis of propene is calculated to be only  $<2 \times 10^3$  molecule  $\text{cm}^{-3} \text{ s}^{-1}$ , if using ozone and propene concentrations listed in Table 2, the rate coefficient  $1.2 \times 10^{-17} \text{ cm}^3 \text{ molec}^{-1} \text{ s}^{-1}$ , and the OH yield of 0.33. This is only  $<20\%$  of the decomposition rate of Criegee intermediates ( $1-2 \times 10^4$  molecule  $\text{cm}^{-3} \text{ s}^{-1}$ ) shown in Figure 5a, suggesting the importance of the other alkenes. Are the other alkenes emitted from anthropogenic activity? Is marine source important for propene?

18.page 7728, lines 17-18 and Figure 6a. It seems from Figure 6a that the main destruction of  $\text{NO}_3$  takes place by the  $\text{NO}_3 + \text{NO}$  reaction, not by the  $\text{NO}_3 + \text{NO}_2$  reaction.

19.page 7729, lines 15-16. It is misleading to mention that  $\text{NO}_2$  was produced from NO, through its reactions with  $\text{CH}_3\text{O}_2$  and  $\text{HO}_2$  and not to mention  $\text{NO}_2$  production from  $\text{NO} + \text{O}_3$  reaction.

20.page 7729, lines 25-27. The ozone decrease by about 30% (or by 10 ppb) cannot be fully attributed to the  $\text{NO}_2 + \text{O}_3$  reaction. It is more likely that  $\text{O}_3$  is titrated by NO during the air mass travel from source region. The NO decrease is influenced by a larger degree by changes in emission and titration, rather than the change in the rate of  $\text{NO}_3 + \text{NO}$  reaction.

21.Figure 8. The flux of the  $\text{CH}_3\text{O}_2 + \text{NO}$  reaction should be specified. It is questionable that the  $\text{HO}_2$  and  $\text{HO}_2\text{NO}_2$  are not well balanced at 23:00 (with flux of +12.5), when  $\text{NO}_2$  concentration did not show a rapid change. Do the  $\text{CH}_3\text{SCH}_2\text{O}_2$  radical and other peroxy radicals produced from  $\text{NO}_3$  reactions produce  $\text{HO}_2$  by their reactions with NO? Is this more important “coupling” between  $\text{NO}_3$  and  $\text{HO}_x$  chemistry rather than the shown ones?

22.page 7730, line 25. It is unclear to what  $\text{HO}_2$  and  $\text{CH}_3\text{O}_2$  are important.

23.Fleming et al. (2005) all over the text should be replaced by Fleming et al. (2006)
