I find the paper interesting and I particularly appreciate author's approach of testing the model in details on case studies before performing a season long simulation. I find, however, relatively frustrating that the case studies and the season simulations are performed at different resolutions. To my opinion, it would be very useful to evaluate the model low resolution configuration at the event scale to better understand its ability on long term scales. A comparison of event simulations at the different model resolutions used would be most useful in this respect.
