A data assimilation method of the Ensemble Kalman Filter for use in severe dust storm forecasts over China by C.Y. Lin, Z.F. Wang, and J. Zhu

General Comments

This paper includes a value application of Ensemble Kalman Filter method for dust storm modeling. The description of this paper is a bit poor (or unfriendly) and need more description to have a better understanding. I think that this paper is suitable for publication to ACP after some minor revision.

Discussion Paper

1. page 17512 Abstract: What does model errors mean ?
2. page 17513 line 5: significant errors must be replaced by significantly model dependent.
3. page 17516 Section 3: this section is very much reader-unfriendly, and need more careful descriptions i) What is parallel assimilation ? ii) What is H in equation (1) iii) What is a, l_x , l_y and l_z iv) What is a range of alpha in equation (5), especially in your application ?
4. page 17518 lines 24-25. Improvement in vertical distribution might be due to vertical diffusion not in background error covariance ?
5. Lidar observation in Figure 6 (most upper panel) needs more careful description. Lidar data is restricted only near the surface on March 20. This might be a missing observation because the dust layer is too thick to prevent the penetration of lidar signal above ?
6. Figure 11 and 12 is difficult to capture the difference (or improvement by EnKF) between with and without EnKF. I recommend preparing the model difference contour additionally.
