Q) The problem of fire and plume dispersion over a tropical forest like Amazon's is a topic of scientific interest that demands research and development of models of the atmospheric circulation since its effect has a local and a remote response as well. The authors intended to improve an 1-D model for fire plume with the inclusion of the entrainment due to the ambient wind. They compare the results of the simple 1-D model with the results of a comprehensive non-hydrostatic 3-D model. The results show that the inclusion of the lateral entrainment effect improves the results and point to the possibility of the module being implemented in a coarser resolution model. In

my opinion, the results are robust enough to deserve being published. Before being accepted the article needs a substantial grammar revision.

A) Thanks for your comments. A proofreading of the text was done.
