If the inverted polarity storms are certainly associated with high liquid water content, then the hypothesis of the charge separation mechanism by ice-ice collisions should be handled with caution, because it has been experimentally determined that this mechanism can lose its efficiency when the ice-particles are close to the wet growth regime (Pereyra et al, JGR, 113, D17203, doi:10.1029/2007JD009720, 2008).

We think that the best way of checking the efficiency of the splinter mechanism is by using a cloud electrification numerical model.

By the way, we will appreciate if the reviewer could suggest some references in literature of the microphysical conditions and charge structures of inverted polarity storms.
