Table list:

Table S1. The SPAMS markers used to search for major groups of oxalic acid particles in this work.

Figure caption:

Figure S1. The topography of Heshan sampling site (22.73N, 112.93E) and its surrounding areas.

Figure S2. The positive and negative mass spectra of oxalic acid measured by SPAMS through standard oxalic acid solution ($400 \mu\text{g}\cdot\text{ml}^{-1}$).

Figure S3. The temporal variation of in-situ pH (pH_{is}) of ambient $\text{PM}_{2.5}$ particles during sampling period in summer.

Figure S4. The clustered 48 hr back trajectories of air masses arriving in Heshan during the sampling period: (a) summer (from July 18 to August 1, 2014), (b) winter (from January 27 to February 8, 2015).

Figure S5. The diurnal variations of in-situ pH (pH_{is}), RH, nitrate, sulfate, ammonium and the free amount of H^+ in aerosols from July 28 to August 1 in 2014.

Figure S6. Temporal variation of organosulfate ($m/z=-155$) containing particles during whole sampling periods in Heshan, China.

Table S1. The SPAMS markers used to search for major groups of oxalic acid particles in this work.

Species	m/z	Marker Ion	Area	Relative Area	Function
Elemental Carbon	12±0.5	[C] ⁺	50	0.005	or
	24±0.5	[C ₂] ⁺	50	0.005	or

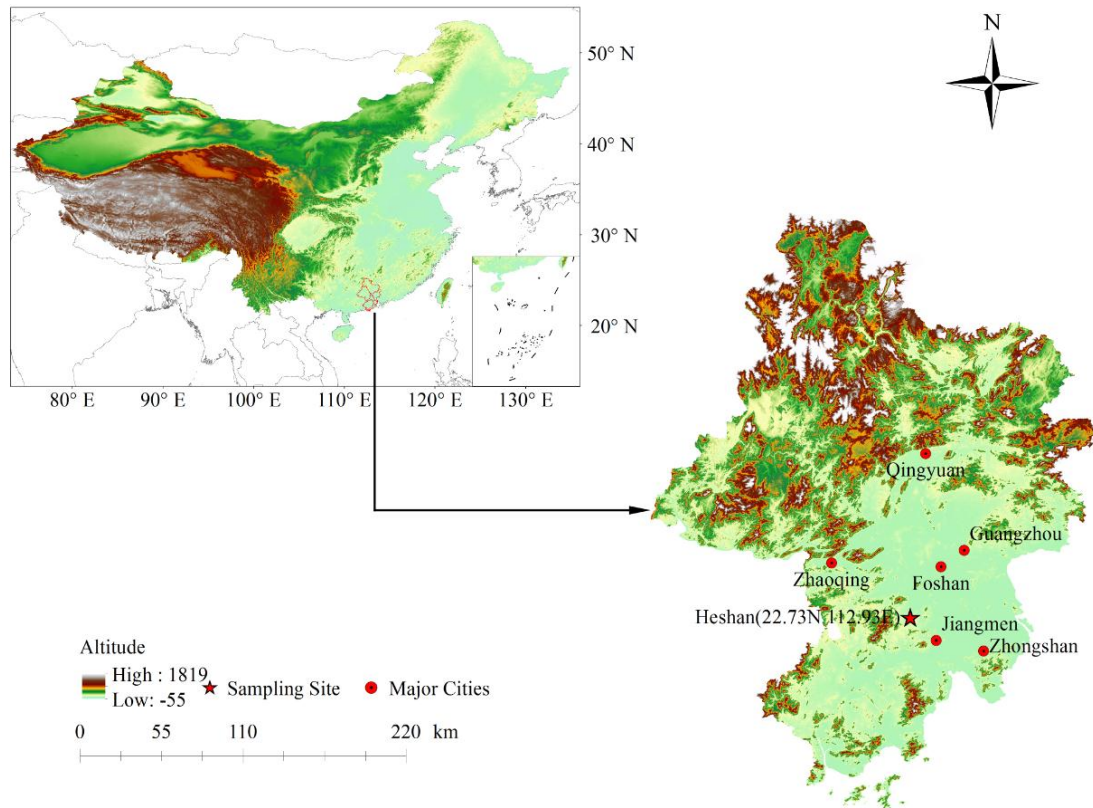

Figure S1. The topography of Heshan sampling site (22.73N, 112.93E) and its surrounding areas.

Figure S2. The positive and negative mass spectra of pure oxalic acid ($\text{H}_2\text{C}_2\text{O}_4$, purity: 99.99%, Aladdin Industrial Corporation) measured by SPAMS through authentic oxalic acid solution ($200 \mu\text{g}\cdot\text{ml}^{-1}$).

The relative area of each fragment refers to the abundance of each peak area in total signal of the mass spectra. The parent ion signal of oxalic acid at mass-to-charge (m/z) -89 (HC_2O_4^-) is significant in the negative mass spectrum. Carbon clusters of $12[\text{C}]^+$, $24[\text{C}_2]^+$, $36[\text{C}_3]^+$ are observed in positive mass spectrum, and $23[\text{Na}]^+$ and $39[\text{K}]^+$ also show peaks due to extremely high sensitivity of SPAMS to these elements which are present as trace impurities (<0.01). HC_2O_4^- (m/z -89) is selected as the marker ion for oxalic acid containing particles. In this work, oxalic acid particles are identified if the peak area of m/z -89 was larger than 0.5% of the total signal in the mass spectrum.

Figure S3. The temporal variation of in-situ pH (pH_{is}) of ambient $PM_{2.5}$ particles during sampling period in summer.

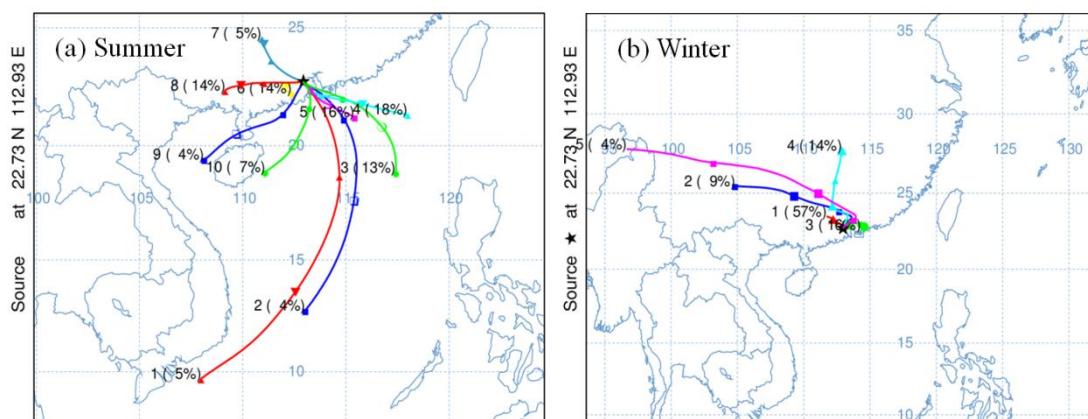

Figure S4. The clustered 48 hr back trajectories of air masses arriving in Heshan during the sampling period: (a) summer (from July 18 to August 1, 2014), (b) winter (from January 27 to February 8, 2015).

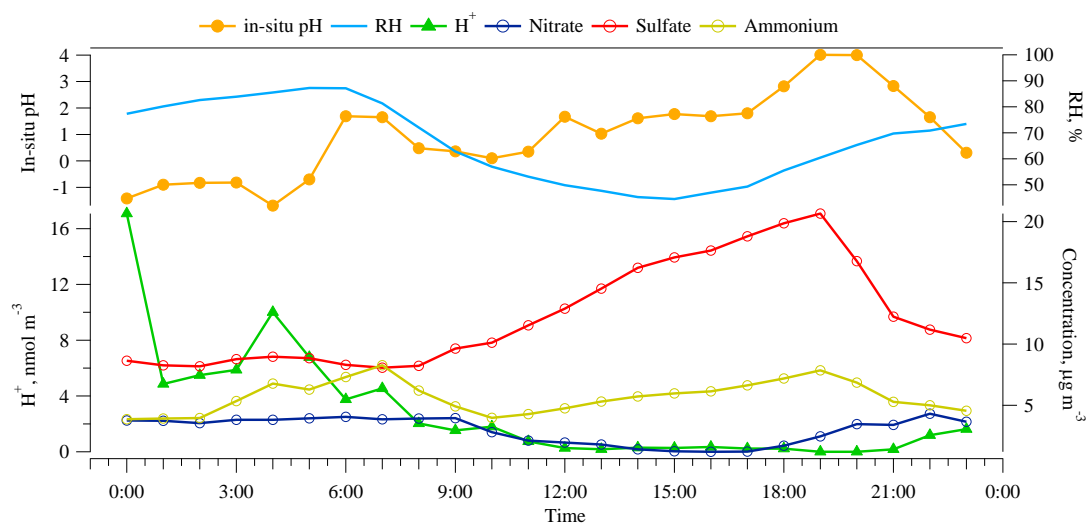

Figure S5. The diurnal variations of in-situ pH (pH_{is}), RH, nitrate, sulfate, ammonium and the free amount of H^+ in aerosols from July 28 to August 1 in 2014.

The pH_{is} of ambient particles ranged from -1.42 to 4.01, which indicate that fine particles in the sampling site are highly acidic. These values are within the range of previous studies that investigated pH_{is} through filter-based and real-time measurements in the PRD area (Xue et al., 2011; Pathak et al., 2004; Yao et al., 2006). Based on the calculation equation, the pH_{is} is determined by the free amount of H^+ and liquid water content (LWC) in the aerosols. LWC is strongly dependent on the ambient RH and affected by water-soluble composition in the aerosols. Thus we investigate the diurnal patterns of RH, major inorganic ions and the free amount of H^+ in Figure S5. Although RH increased from 0:00 to 7:00, H^+ had higher concentration during this period than the other time, which resulted the lower value of pH_{is} (between -1.42 and 0) from 0:00 to 5:00. Thus more acidic aerosols with pH_{is} below 0 were observed due to the combined effects of the RH and relative abundance of H^+ in aerosols.

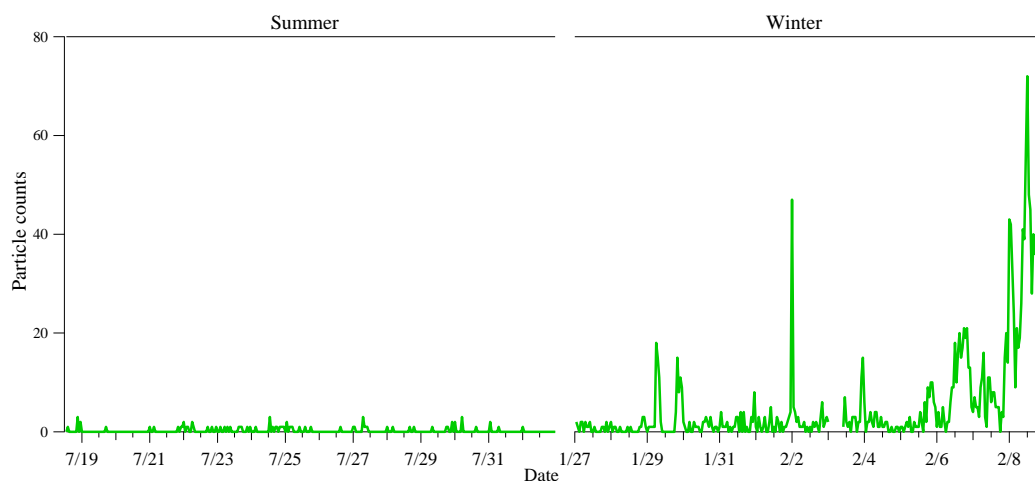

Figure S6. Temporal variation of organosulfate ($m/z=-155$) containing particles during whole sampling periods in Heshan, China.

The organosulfate derived from reaction between glyoxal and sulfuric acid was identified at $m/z=-155$ ($[C_2H_3O_2SO_4]^-$) based on previous work conducted by Surratt (Surratt et al., 2007; Surratt et al., 2008) and Hatch (Hatch et al., 2011) in chamber and field measurements. In current work organosulfate-containing particles were identified if the relative peak area of $m/z -155$ was larger than 0.5%. With this threshold, 78 and 1874 of organosulfate particles were obtained in summer and winter separately, accounting for 0.01% and 0.25% in each total detected particles.
