26 **Abstract**

27

28 We measured peroxyacetyl nitrate (PAN) and other reactive species such as O₃, NO₂, CO,
29 and SO₂ with aerosols including mass, organic carbon (OC), and elemental carbon (EC) in
30 PM_{2.5} and K⁺ in PM_{1.0} at Gosan Climate Observatory in Korea (33.17°N, 126.10°E) during
31 October 19 to November 6, 2010. PAN was determined through fast gas chromatography
32 with luminol chemiluminescence detection at 425 nm every 2 min. The PAN mixing ratios
33 ranged from 0.1 (detection limit) to 2.4 ppbv with a mean of 0.6 ppbv. For all measurements,
34 PAN was unusually better correlated with PM_{2.5} (Pearson correlation coefficient, $\gamma = 0.79$)
35 than with O₃ ($\gamma = 0.67$). In particular, the O₃ level was highly elevated with SO₂ at midnight,
36 along with a typical midday peak when air was transported rapidly from the Beijing areas.
37 The PAN enhancement was most noticeable during the occurrence of haze under stagnant
38 conditions. In Chinese outflows slowly transported over the Yellow Sea, PAN gradually
39 increased up to 2.4 ppbv at night, in excellent correlation with a concentration increase of
40 PM_{2.5} OC and EC, PM_{2.5} mass, and PM_{1.0} K⁺. The high K⁺ concentration and OC/EC ratio
41 indicated that the air mass was impacted by biomass combustion. This study highlights PAN
42 decoupling with O₃ in Chinese outflows and suggests PAN as a useful indicator for
43 diagnosing continental outflows and assessing their perturbation on regional air quality in
44 northeast Asia.

45

46 Key words: PAN, O₃, PM_{2.5}, Chinese outflow, Haze, Biomass combustion

47 1. Introduction

48

49 At the surface, ozone is primarily photochemically produced, and the contribution from the
50 stratosphere is generally small. Ozone is formed through reactions of various precursors such
51 as CO, CH₄, volatile organic compounds (VOCs), and NO_x (e.g., Brasseur et al., 1999; Jacob,
52 2000; Nielsen et al., 1981). Likewise, peroxyacetyl nitrate (PAN) is a secondary product of
53 urban air pollution and a significant oxidant in the atmosphere (e.g., Hansel and Wisthaler,
54 2000; La Franchi et al., 2009; Lee et al., 2012; Liu et al., 2010; Roberts et al., 2007). PAN is
55 solely produced by the photochemical reaction between the peroxyacetyl radical and nitrogen
56 dioxide, and the peroxyacetyl radical is derived from the OH oxidation or photolysis of
57 VOCs such as acetaldehyde, methylglyoxal, and acetone (e.g., Fischer et al., 2014; La
58 Franchi et al., 2009; Lee et al., 2012). For this reason, PAN is a very useful indicator of
59 photochemical air pollution. As thermal decomposition is a major PAN sink in the
60 troposphere (Beine et al., 1997; Jacob, 2000; Kenley and Hendry, 1982; Talukdar et al., 1995),
61 the lifetime of PAN depends on temperature. For example, the PAN lifetime is ~5 years at
62 -26°C and 1 h at 20°C (Fischer et al., 2010; Zhang et al., 2011). At high altitudes above ~7
63 km, photolysis becomes the most important loss process for PAN (Talukdar, et al., 1995).
64 Because of low solubility, PAN is not prone to atmospheric removal, thereby being more
65 efficiently transported to the free troposphere (e.g., Zhu et al., 2017). Thus, PAN can be an
66 indicator of NO_y concentration in the free troposphere and a guide for the long-range
67 transport of NO_x in remote regions (Jacob, 1999).

68 In the past decades, PAN was measured not only in urban areas (Aneja et al., 1999;
69 Gaffney et al., 1999; Grosjean et al., 2002; Lee et al., 2008; Tanimoto et al., 1999; Zhang et
70 al., 2014) but also in background regions (Fischer et al., 2011; Kanaya et al., 2007; Lee et al.,

71 2012; [Tanimoto et al., 2002](#)), onboard aircraft ([Tereszczuk et al., 2013](#)), and ships ([Roberts et](#)
72 [al., 2007](#)). PAN concentrations were in the range of a few ppbv in urban areas close to VOCs
73 and NO_x sources ([Lee et al., 2008](#); [Zhang et al., 2011](#)). In [the most](#) remote regions, PAN
74 [concentrations](#) were generally in the range of a few pptv ([Gallagher et al., 1990](#); [Mills et al.,](#)
75 [2007](#); [Muller and Rudolph, 1992](#); [Staudt et al., 2003](#)).

76 [Although NO_x concentration has recently declined in China \(\[Gu et al., 2013\]\(#\); \[Liu et al.,\]\(#\)](#)
77 [2016a](#); [Krotkov et al., 2016](#)), NO_x and VOCs have gradually increased in East Asia,
78 [particularly China during the last couple of decades \(\[Akimoto, 2003\]\(#\); \[Liu et al., 2010\]\(#\); \[Ohara\]\(#\)](#)
79 [et al., 2007](#); [Zhao et al., 2013](#)). It led to an increase in the concentrations of photochemical
80 [byproducts such as PAN and O₃ not only in East Asia \(\[Liu et al., 2010\]\(#\); \[Wang et al., 2010\]\(#\);](#)
81 [Zhang et al., 2009](#); [Zhang et al., 2011](#); [Zhang et al., 2014](#)) but also in North America ([Fischer](#)
82 [et al., 2010](#); [Fischer et al., 2011](#); [Jaffe et al., 2007](#); [Zhang et al., 2008](#)). These results were
83 [also demonstrated by the GEOS-Chem model \(\[Zhang et al., 2008\]\(#\)\). In addition to urban](#)
84 [plumes, PAN was reported to be enhanced by biomass combustion \(\[Alvarado et al., 2010\]\(#\);](#)
85 [Coheur et al., 2007](#); [Zhu et al., 2015](#); [Zhu et al., 2017](#)), such as open burning and use of
86 [biofuel, which is used to take place often in China after crop harvesting \(\[Cao et al., 2006\]\(#\);](#)
87 [Duan et al., 2004\). Recent satellite studies have also observed the increased PAN in plumes](#)
88 [associated with anthropogenic emissions in eastern China and boreal fires in Siberia \(\[Zhu et\]\(#\)](#)
89 [al., 2015](#); [Zhu et al., 2017](#)). In this context, PAN is a useful tracer for estimating the impact of
90 [Chinese outflows on regional air quality in the northern Pacific region.](#)

91 Gosan Climate Observatory (GCO) is an ideal place to monitor Asian outflows and their
92 transformation and to estimate their impact on air quality over the northern Pacific region
93 ([Lee et al., 2007](#); [Lim et al., 2012](#)). In the present study, PAN was first measured
94 continuously at GCO to characterize its variation and source in relation to O₃ and to

95 understand the influence of Chinese outflows on the regional air quality.

96

97 **2. Experiments**

98

99 PAN measurements were conducted at GCO (33.17°N, E126.10°E) on Jeju Island from
100 October 19 to November 6, 2010. GCO is located on a cliff at the western edge of Jeju Island.
101 PAN was determined through fast gas chromatography (GC) with luminol
102 chemiluminescence detection, which is described in detail elsewhere (Gaffney et al., 1998;
103 Lee et al., 2008; Marley et al., 2004). Here, we briefly describe the measurement method.

104 Ambient air was pumped through a 1.6-m PFA tubing (1/4 inch outer diameter) from the
105 roof of the two-story container into a six-port injection valve (Cheminert C22, Valco
106 Instruments (Houston, TX, USA)) at 100 ml/min controlled by Mass flow controller (Lee et
107 al., 2012; Lee et al., 2008). The residence time of the inlet was less than 2 seconds. PAN and
108 NO₂ (and peroxypropyl nitrate (PPN) if present) were separated along a 10-m capillary GC
109 column (DB-1, J&W Scientific, Folsom, CA, USA), whose end was connected to a luminol
110 cell where the column effluent reacted with luminol, giving off luminescent light (Lee et al.,
111 2008; Lee et al., 2012). The concentrations of PAN and other species were determined from
112 the chemiluminescence signals detected by a gated photon counter (HC135-01, Hamamatsu,
113 Bridgewater, NJ, USA) at 425 nm, which was set at 800 V and operated at room temperature
114 (Gaffney et al., 1998; Lee et al., 2012; Lee et al., 2008).

115 PAN was calibrated against standards synthesized by the nitration of peracetic acid in n-
116 tridecane (Gaffney et al., 1984; Gregory, 1990; Lee et al., 2008). A few microliter aliquots of
117 standard solution were injected through an injection valve and then mixed with zero air
118 (99.999 %) in a 5 L Tedlar bag. After being left for a few minutes for equilibrium, it was

119 injected into GC-luminol instrument and NO_x chemiluminescence instrument with a
120 molybdenum converter (42C, Thermo Electron Corporation, Franklin, MA, USA). The
121 calibration was completed within 5 minutes to prevent thermal decomposition of the PAN
122 (Kourtidis et al., 1993; Lee et al., 2008). These calibration procedures were carried out on the
123 assumption that the PAN was completely converted to NO in the molybdenum converter. The
124 detection limit of PAN defined by 3 σ of the lowest standard was no greater than 100 pptv
125 (Lee et al., 2008). The overall measurement uncertainty and precision was estimated to be 16 %
126 and 5%, respectively (Lee et al., 2012). NO_x instrument was calibrated with NO standard gas.

127 Gaseous species including O₃, NO, NO₂, CO, and SO₂ were measured by UV absorption,
128 chemiluminescence with a molybdenum converter, non-dispersive infrared, and pulse UV
129 fluorescence method, respectively (NIER, 2016a). The measurements were made in
130 compliance with guidelines for installation and operation of air pollution monitoring network
131 (NIER, 2016b). Calibration was conducted before and after the experiment, following the
132 regular checkup procedure. Detection limits of O₃, NO_x, CO, and SO₂ are 2 ppb, 0.1 ppb, 50
133 ppb, 0.1 ppb, respectively (NIER, 2016b).

134 Aerosol species, including PM_{2.5} mass and PM_{2.5} OC and EC were measured and recorded
135 along with meteorological parameters (relative humidity, temperature, and wind **direction** and
136 speed). Water-soluble ions of PM_{1.0} were collected by a particle-into-liquid sampler (PILS)
137 and analyzed by ion chromatography. The detailed results of the aerosol measurements can be
138 found in Shang et al. (2017).

139 For the air parcel at 850 m a.s.l., the three-day backward trajectories were calculated every
140 hour using NOAA Air Resources Laboratory (ARL) Hybrid Single-Particle Lagrangian
141 Integrated Trajectory (HYSPLIT) model (version 4) (Draxler and Rolph, 2012; Rolph, 2012,
142 <http://www.arl.noaa.gov/ready/hysplit4.html>). In addition, O₃ and PAN concentrations were

143 calculated using a global chemistry model, the Community Atmosphere Model with
144 Chemistry (CAM-Chem), a component of the Community Earth System Model (CESM)
145 (Lamarque et al., 2012; Tilmes et al., 2015). The CAM-chem results shown here follow the
146 configuration used for the HTAP2 (Hemispheric Transport of Air Pollution, Phase 2)
147 intercomparison (e.g., Stjern et al., 2016). CAM-chem is nudged to observed meteorology
148 (GEOS-5) to reproduce the actual period of the observations (Oct 2010). The emissions used
149 in the model are the HTAP2 inventory (Janssens-Maenhout, et al., 2015), which include the
150 "MIX" Asian emissions inventory. Biomass burning emissions are from the Global Fire
151 Emissions Database (GFED3) (Randerson et al., 2013).

152

153 **3. Results**

154

155 In the present experiments, PAN concentrations range from 0.1 to 2.4 ppbv, with an
156 average of 0.6 ppbv. This mean value is lower than those observed in other Asian megacities:
157 Beijing (1.41 ppb in the summer), Pearl River Delta region (1.32 ppb in the summer), and
158 Seoul (0.8 ppb in the early summer); similar to those of suburban areas in China, e.g.,
159 Lanzhou (0.76 ppb in the summer); and higher than those of urban and rural sites in Japan,
160 e.g., Tokyo (up to 0.6 ppb in the fall), Rishiri Island (~0.5 ppb in spring) or in the western
161 coast of the US, e.g., Sacramento (0.45 ppb in the summer), Mt. Bachelor (0.144 ppb in the
162 spring and early summer), off the western coast of the US (0.65 ppb in the spring), and over
163 the remote North Pacific (total PAN < 0.3 ppb in spring) (Bertram et al., 2013; Fischer et al.,
164 2011; La Franchi et al., 2009; Lee et al., 2008; Roberts et al., 2004; Tanimoto et al., 1999;
165 Tanimoto et al., 2002; Wang et al., 2010; Zhang et al., 2009; Zhang et al., 2011). Because the
166 PAN lifetime is greatly dependent on temperature, its concentration decreases with increasing

167 distance from the source regions. The PAN concentrations calculated in this study thus lie in-
168 between the levels for the East Asian megacities and the northern Pacific. The distributions of
169 all measured species, including PAN and O₃, are presented in Fig. 1. In particular, there are
170 several periods characterized by high concentrations of PAN, O₃, and PM_{2.5}. In terms of PAN,
171 four periods are particularly interesting (Fig. 1). High O₃ concentrations were observed
172 during October 31–November 2 [episode 1] but did not coincide with high PAN
173 concentrations. During October 28–29 [episode 2], NO₂ was noticeably increased. In
174 comparison, PAN and O₃ concentrations were both high during October 20–21 [episode 3]
175 and November 4–5 [episode 4]. Episodes 3 and 4 are characterized by haze, while episodes 1
176 and 2 are characterized by urban influence in the Korean and Beijing outflows, respectively.
177 Haze is reported by Korea Meteorological Administration (KMA) as a meteorological
178 phenomenon when visibility is 1~ 10 km and relative humidity is less than 75 %.

179 In the present study, PAN correlates reasonably well with O₃ ($\gamma = 0.67$) and even better
180 with PM_{2.5} ($\gamma = 0.79$). In general, O₃ and PAN exhibit typical diurnal variation with a
181 maximum recorded in the afternoon, which results in a good correlation between the two
182 (Brasseur et al., 1999; Gaffney et al., 1999; Ridley et al., 1990; Schrimpf et al., 1995; Wang
183 et al., 2010). In this study, however, the O₃ peak was often found in the early morning and
184 late afternoon for several days (Fig. 1). Observing the diurnal variations in the entire PAN
185 concentration measurement set (Fig. 2), the maximum was clearly recorded in the morning
186 with the highest outliers, which is rather similar to that of PM_{2.5}. The diurnal pattern of NO₂
187 shows little variation, even though its concentrations were increased in the morning along
188 with PAN. This first measurement of PAN at GCO reveals that PAN is not always coupled
189 with O₃, which was not typically observed at remote sites in previous studies (e.g., Fischer et
190 al., 2010; Lee et al., 2012).

191

192 4. Discussion

193 4.1. Decoupling of PAN from O₃

194

195 To examine the detailed mechanism of the decoupling of PAN from O₃, the daily
196 maximum concentrations of PAN and O₃ were further explored. The recorded daily PAN
197 maxima were generally in good correlation with O₃, albeit the relationship did not seem to
198 hold at high concentrations of PAN and O₃ (Fig. 3). The daily maxima were then categorized
199 into four groups according to the time when each O₃ and PAN maximum was recorded: “O₃
200 day-PAN day”, “O₃ day-PAN night”, “O₃ night-PAN day”, and “O₃ night-PAN night”. The
201 day interval started from 08:00 and ended at 18:00 (local time), based on the times of sunrise
202 and sunset during the experiment period. While the high PAN concentrations were associated
203 with the “O₃ day-PAN day” group (cross symbols in Fig. 3), the enhanced O₃ concentration
204 was recorded in the “O₃ night-PAN night” group (star symbols in Fig. 3). The “O₃ night-PAN
205 night” group unexpectedly held more data points than the “O₃ day-PAN day” group, even
206 though the “O₃ night-PAN night” group concentrations were lower (Fig. 3). In addition, there
207 were several days classified in the “O₃ night-PAN day” (marked by diamond) and “O₃ day-
208 PAN night” groups, but with less frequency and lower concentrations. These results indicate
209 that the decoupling of PAN from O₃ was primarily due to the elevated concentrations of O₃
210 and PAN at night. While PAN reached the maximum during the day on Oct 20 and Nov 5,
211 their concentrations were increased from the previous day through the night. The four high
212 PAN and O₃ episodes identified in this study fall under the category of “O₃ night-PAN night”
213 or “O₃ day-PAN day”. These two cases will be further examined to identify the chemical and
214 physical processes responsible for PAN being decoupled from O₃, instead of being coupled

215 with $PM_{2.5}$. The overall characteristics of the four episodes are summarized in Table 1.

216

217 **4.2. Export of O_3 from Asian continents (episodes 1 & 2)**

218

219 High O_3 concentrations were encountered around midnight on three consecutive days from
220 October 31 to November 2 (episode 1), during which SO_2 reached its maximum
221 concentration (Fig. 1). The backward trajectories of air masses revealed that air passed
222 through the Beijing area during this period (Fig. 4). *The strong wind (13.5 m/s on average)*
223 *implies that it would take about a day for air mass leaving Beijing area to arrive at GCO.*
224 The recorded O_3 maximum (80.6 ppbv) was concurrent with the PAN maximum (0.9 ppbv)
225 around midnight on November 1st (Fig. 1). All these results indicate that the air was heavily
226 influenced by outflow from the Beijing area, as previously hypothesized (Lim et al., 2012),
227 and that *the nighttime enhancement of O_3 and PAN with SO_2 resulted from the fast transport*
228 *of urban plumes from China.*

229 In previous studies, the nighttime enhancement of O_3 was observed at GCO (e.g., Lee et al.,
230 2007) in association with pollutant-laden air coming from Beijing. Similarly, Banta et al.
231 (1998) pointed out that the evening O_3 maximum was due to long-range transport of O_3 from
232 nearby urban areas. Wang et al. (2011) reported that the O_3 lifetime was about two days in
233 East China during the summer, *which is sufficient for O_3 to travel to GCO but not for PAN*
234 *due to its short lifetime.* Therefore, the nighttime maximum of O_3 can be attributed to the
235 export of O_3 from megacities in China, causing PAN to be decoupled from O_3 . *Because the*
236 *overall correlation between O_3 and PAN was the best with the highest $\Delta O_3/\Delta PAN$ among all*
237 *cases discussed in this study (Fig. 5a), episode 1 likely represents an event of rapid transport*
238 *from the Beijing area.*

239 Another night maximum of O_3 was recorded on October 29. Note that NO_x was highly

240 elevated with the lowest SO₂ concentrations during October 28–29 (episode 2) (Fig. 1). In
241 episode 2, O₃ concentrations were much lower and poorly correlated with those of PAN,
242 compared to episode 1. Instead, PAN was best correlated with NO₂ with the highest
243 $\Delta\text{NO}_2/\Delta\text{PAN}$ among all episodes (Fig. 5a, b). In this case, air masses passed through the
244 Korean Peninsula, carrying low O₃ being titrated by high NO_x (Brasseur et al., 1999;
245 Jacobson, 2005). These two episodes illustrate the export of urban plumes in northeast Asia
246 region, which are distinguished by relative enhancement of reactive gases including O₃, PAN
247 and NO_x, depending on the origin and aging of air masses.

248

249 **4.3. PAN enhancement upon occurrence of haze (episodes 3 & 4)**

250

251 In this study, two haze events were observed in the very beginning (October 20–21;
252 episode 3) and the end of the study period (November 4–5; episode 4). As the nighttime O₃
253 peak was attributed to the transport from nearby urban areas to Jeju Island, the two haze
254 episodes were also observed in association with continental outflows. The first haze event
255 occurred on October 18th and lingered until October 21st, during which O₃ concentrations
256 were gradually elevated. A second peak was recorded around midnight of October 19th and
257 20th, and the maximum was reached in the afternoon of October 20th (Figs. 1 and 3). In this
258 episode, the maximum concentrations of O₃ and PAN were 78.9 ppbv and 2.0 ppbv,
259 respectively, on October 20th, when the highest NO₂ concentration (12.7 ppbv) was observed
260 under low wind speed (6.6 m/s daily average). The air mass trajectories suggest the influence
261 of the Korean Peninsula, particularly the Seoul metropolitan area, in addition to East China
262 (Fig. 4).

263 In the second haze event (episode 4), an air mass was slowly transported from East China,

264 including the Jiangsu province, under stagnant condition which was developed by an
 265 anticyclone system (Fig. 4). We measured the highest concentrations of all aerosol species
 266 including the $PM_{2.5}$ mass as well as PAN and O_3 , which were $156 \mu\text{g}/\text{m}^3$, 2.4 ppbv, and 87.5
 267 ppbv, respectively. Other reactive gases such as CO, SO_2 , and NO_2 were also highly elevated.
 268 Note that PAN and O_3 gradually increased through the night, leading to a nighttime maximum
 269 of both species on November 4th. It is likely that the pre-formed PAN and O_3 were
 270 continuously transported into Gosan at night.

271 PAN is formed through the reaction of the peroxyacetyl radical and nitrogen dioxide (Eq. 1)
 272 and decomposed at high temperature (Eq. 2), returning these radicals. Unless the NO
 273 concentration is high (Eq. 3), the peroxyacetyl radical recombines with NO_2 , producing PAN.
 274 Thus, the total lifetime of PAN depends on the NO_2/NO ratio and temperature (Eq. 4)
 275 (Brasseur et al., 1999).

$$279 \quad T_{eff} = T_d \left(1 + \frac{k_1[\text{NO}_2]}{k_2[\text{NO}]} \right) [\text{sec}^{-1}] \quad (4)$$

280 where T_d and T_{eff} indicate the lifetime against decomposition and the effective lifetime of
 281 PAN (Brasseur et al., 1999). The effective lifetime of PAN was estimated through Eq. 4 using
 282 the rate constants proposed by Brasseur et al. (1999), Jacobson (2005), and Maricq and
 283 Szente (1996).

284 During the haze event, NO was close to the detection limit, while NO_2 was greatly
 285 enhanced. Owing to the high NO_2/NO ratio, the effective lifetime of PAN increased by 57
 286 times; this possibly contributed to the gradual increase in PAN through the night on
 287 November 4th. Fischer et al. (2014) also reported that, at night, PAN can be produced from
 288 the reaction of acetaldehyde with the nitrate radical.

289 Besides $PM_{2.5}$ mass, PAN was also well correlated with $PM_{2.5}$ OC and EC not only during
290 this haze episode but also during the entire measurement period (Fig. 6a and b). Furthermore,
291 the enhancement of PAN was concurrent with that of OC and K^+ , resulting in excellent
292 correlation between them (Fig. 6b and d). In fact, the $\Delta OC/\Delta EC$ ratio of episode 4 was much
293 higher (7) than those of the other episodes (~ 2.5) (Fig. 6c). The fraction of $PM_{2.5}$ against
294 PM_{10} was also the highest in this episode, indicating significant contribution of secondary
295 aerosols. These observations suggest that air masses were affected by biomass combustion
296 (e.g., Ram et al., 2008, 2012; Saarikoski et al., 2008).

297 According to previous studies, PAN can be produced in plumes through biomass
298 combustion (Alvarado et al., 2010; Coheur et al., 2007; Liu et al., 2016b; Tereszchuk et al.,
299 2013). In northeast China, open burnings related to agricultural activities frequently occur
300 during the spring and fall (Duan et al., 2004; Yang et al., 2005). Kudo et al. (2014) also
301 reported that, upon burning crop residue in Yangtze region, the levels of oxygenated VOCs
302 were elevated together with NO_x . In addition, biofuel is used for cooking and heating and as
303 an energy source in China's industry (Cao et al., 2006).

304 Therefore, PAN is likely to increase when haze occurs and fine aerosols are transformed as
305 air masses carrying combustion emissions are slowly transported from China over the Yellow
306 Sea. Additionally, the results of this study imply that PAN can be used as a robust tracer for
307 continental outflows in northeast Asia, to identify transport- and chemical transformation-
308 dominant regimes. In a transport-dominant regime, O_3 export was distinguished by the
309 highest levels of primary gaseous species such as SO_2 and relatively low levels of PAN. In
310 contrast, fine aerosol species were enhanced in a chemical transformation regime, leading to
311 haze events with relatively more enhanced PAN compared to O_3 .

312 Finally, the measured O_3 and PAN concentrations were compared to results from a global

313 chemistry model CAM-Chem. In the model simulation, O₃ and PAN were highly
314 underestimated during the episodes observed in Chinese outflows, although the variation
315 around average level of O₃ and PAN was well captured (Fig. 7). The elevated PAN
316 concentration was underestimated in the model (Oct 20–21 and Nov 4–5), especially when air
317 was impacted by biomass combustion. The timing of the O₃ diurnal variability was captured
318 by the model, although the magnitude of the variation was underestimated. These results
319 reveal that the current understanding of Chinese outflow is still not sufficient, thereby causing
320 uncertainty in estimating its effect on air quality in the northwestern Pacific Rim.

321

322 5. Conclusions

323

324 The first measurements of PAN, reactive gases, and aerosol species were conducted at
325 GCO during October 19 to November 6, 2010. The average concentration of PAN was 0.6
326 ppbv with a maximum of 2.4 ppbv, which was lower than those in major cities in East Asia
327 but much higher than the background concentrations in other regions. Although the hourly
328 concentrations of PAN and O₃ were well correlated ($\gamma = 0.67$), the comparison of the daily
329 maxima of PAN and O₃ highlighted that they were not proportionally enhanced. That is,
330 either PAN was relatively more elevated than O₃ or the highest O₃ was associated with low
331 levels of PAN. Unexpectedly, both PAN and O₃ often reached their maxima at night. In this
332 study, these high concentrations were all encountered in association with continental outflows,
333 where PAN was decoupled from O₃ and better correlated with the PM_{2.5} mass ($\gamma = 0.79$) than
334 with O₃. Thus, two high-O₃ and two high-PAN events were the most clearly distinguished
335 and investigated in detail.

336 During the O₃ episodes, both O₃ and PAN concentrations reached their maximum values at

337 night. In episode 1 (Oct. 31 to Nov. 2), the O₃ concentration was increased to 80.6 ppbv, with
338 a high SO₂ concentration under strong wind. It was a typical Beijing plume observed in the
339 study region. In comparison, NO₂ was greatly increased in episode 2 (Oct. 28–29) when the
340 air masses were affected by urban emissions from Korean Peninsula. Although the maximum
341 O₃ level was lower during episode 2, these two cases demonstrated well how O₃ was exported
342 from the East Asian continent.

343 The remaining two episodes were highlighted by enhanced PAN concentrations and
344 characterized by haze occurrence. During episode 3 (Oct. 20–21), PAN and O₃ concentrations
345 increased up to 2.0 ppbv and 78.9 ppbv, respectively, with high NO_x levels, probably
346 influenced by emissions from Korea. Episode 4 (Nov. 4–5) was characterized by the highest
347 concentrations of almost all measured species, including PAN, O₃, PM_{2.5} mass, and PM_{1.0}
348 species; the maximum recorded concentrations of PAN, O₃, and PM_{2.5} mass during this
349 interval were 2.4 ppbv, 87.5 ppbv, and 156 μg/m³, respectively. Note that, along with PM_{2.5}
350 and O₃, PAN was gradually increased through the night. In this episode, an air mass was
351 slowly transported from eastern China. With depleted NO, the effective lifetime of PAN was
352 greatly extended. In addition, PAN concentration showed good correlation with OC, EC, and
353 K⁺; in fact, the correlation of PAN with K⁺ was comparable to that of OC with K⁺. These
354 results, in conjunction with the high OC/EC (7), imply that the observed haze was mainly
355 caused by the emissions produced by biomass combustion. These results suggest that PAN is
356 a useful tool for distinguishing continental outflows that were typically observed in northeast
357 Asia.

358 The comparison between the measured and calculated concentrations using the CAM-
359 Chem-HTAP2 model showed that the model underestimated the O₃ and PAN levels in
360 Chinese outflows, particularly for haze incidence. These results reveal that Chinese outflows

361 are still poorly understood and not well captured in the model.

660 **Tables**

661

662 Table 1. Chemical and meteorological characteristics of the four episodes.

	Episode 1	Episode 2	Episode 3	Episode 4
Period	Oct.31 ~ Nov.2	Oct. 28~29	Oct. 20~21	Nov. 4~5
Type	Transport dominant	Transport dominant	Chemical transformation	Chemical transformation
Event	O ₃ export	O ₃ export	Haze	Haze
O ₃ (ppbv)	60.2 (80.6)	45.6 (62.8)	59.7 (78.9)	61.8 (87.5)
PAN (ppbv)	0.5 (0.9)	0.5 (0.8)	1.2 (2.0)	1.3 (2.4)
PM _{2.5} (μg/m ³)	34 (62)	23 (36)	50 (76)	77 (156)
SO ₂ (ppbv)	4.3 (12.9)	2.0 (4.4)	2.6 (5.4)	4.4 (9.5)
NO ₂ (ppbv)	3.7 (7.3)	6.2 (12.1)	6.2 (12.7)	6.1 (9.9)
Wind Speed (m/s)	13.5 (16.0)	9.5 (16.1)	6.6 (10.2)	5.0 (7.7)

663 *Measurements are given for the average with the maximum in the parenthesis.

664 **Figure Captions**

665

666 Figure 1. Temporal variations (against local time) of measured species, including PAN, $PM_{2.5}$,
667 O_3 , NO_2 , NO , SO_2 , and, CO , and meteorological parameters, including relative
668 humidity, temperature, and wind speed in fall 2010. Episodes 1–4, described in the
669 main text, are shaded in blue and yellow.

670 Figure 2. Diurnal variations in the concentrations of O_3 , NO_2 , PAN, and $PM_{2.5}$, measured at
671 GCO in the fall of 2010 (5 min data of O_3 , NO_2 , 2 min data of PAN, and 1 h data of
672 $PM_{2.5}$).

673 Figure 3. Comparison of O_3 with the PAN daily maxima. The time when the daily maximum
674 appears is classified as daytime (08–18 h) and nighttime (the rest) based on the
675 time of sunrise and sunset. Numerals indicate the days.

676 Figure 4. The three-day NOAA HYSPLIT backward trajectories of air masses for every one
677 hour observed at GCO during episode 1 (Oct. 31 to Nov. 2), episode 2 (Oct. 28–29),
678 episode 3 (Oct. 20–21), and episode 4 (Nov. 4–5). They are colored according to
679 the level of (a) PAN, (b) O_3 , (c) NO_2 , and (d) $PM_{2.5}$ at GCO at the time of the
680 trajectory initialization. The trajectories north of $50^\circ N$ are not shown. For these
681 horizontal trajectories, (e) vertical heights are given.

682 Figure 5. Correlations between (a) PAN and O_3 and (b) PAN and NO_2 with linear regression
683 line for each episode. Correlations between O_3 and PAN were color coded by the
684 level of (c) NO_2 and (d) $PM_{2.5}$.

685 Figure 6. Correlations among PAN, K^+ ion of $PM_{1.0}$, and carbonaceous components of $PM_{2.5}$
686 for three cases: (a) PAN and $PM_{2.5}$ mass, (b) PAN and $PM_{2.5}$ OC, (d) $PM_{2.5}$ EC and
687 OC, and (d) PAN and $PM_{1.0}$ K^+ . The lines represent the linear regression for each
688 episode.

689 Figure 7. Comparison between the observed and calculated (a) PAN and (b) O_3
690 concentrations by CAM-chem model. Time is given in local time and four episodes
691 are shaded.
