

S1. Characterization of Experimental Chamber

Known amounts of NO₂ in N₂ were flowed through the sample illumination chamber and IBBCEAS cell in order to characterize the observed HONO for different experimental variables. The current set up facilitates an efficient NO₂ surface hydrolysis, forming HONO. Results are shown in Fig. S1 for both dark and light experiments as a function of RH. An input NO₂ concentration of 6.0 ppm, based on the reported value from the supplier (Linde), was further diluted with N₂ using needle valves and mass flow meters with uncertainties of ± 0.5 mL/min. The figure displays the measured NO₂ and HONO concentrations detected by the IBBCEAS as a function of RH. The total concentration measured from the sum of NO₂ and twice the HONO calculation following the mass balance implied by Equation 1, is within error of that calculated from the NO₂ concentration coming from the cylinder: $(3.6 \pm 0.3) \times 10^{12}$ molecules/cm² measured compared to $(4.76 \pm 2.4) \times 10^{12}$ molecules/cm² calculated from the dilution of the NO₂ cylinder. This suggests that this technique can quantify the total concentration of NO₂ + HONO here, though cannot accurately speciate NO₂ and HONO. Fig. S1b shows that the total concentration decreases upon illumination, due to the photolysis of NO₂ and HONO. The HONO concentration measured is independent of relative humidity within the 30% coefficient of variability measured between samples. No NO₂ was detected. This shows that the NO₂ to HONO conversion is complete within error, and that there is no significant impact on the IBBCEAS NO₂ + HONO response as a function of relative humidity. We note that, if the photochemical product distribution between NO₂ and HONO changes with relative humidity, this will impact the total amount measured because it takes two NO₂ molecules to make one HONO molecule. Thus a change from only NO₂ production to only HONO production would appear as a 50% change in the total amount detected as HONO. However, the changes measured as a function of RH are larger than can be explained by this mechanism.

Thus the total product concentrations from grime photochemistry may be safely compared as a function of RH. No values are shown below 13% in Fig. 3 and Fig. S1 because the RH meter is not sensitive below 10% and thus we cannot accurately report RH values. As well, when N₂ is flowed through the chamber without humidification, the total signal for NO₂ and HONO does not reach a plateau even after one hour. This indicates that the NO₂ is being irreversibly lost to the walls, likely forming complexes with the metal (Nishino and Finlayson-Pitts, 2012).

Figure S1: Concentrations of HONO and NO₂ for NO₂ flowed through the chamber and IBBCEAS cell as a function of RH a) in the dark and b) in the light. Only HONO concentrations are shown in Fig. S1b because no NO₂ was detected. The error bars represent one standard deviation of the average of three experiments.
