### 1 PCVI characterization

Characterization of the transmission efficiency of the PCVI was carried out using the method described by Kupiszewski et al. (2015) and was conducted as follows: Arizona Test Dust (ATD) was dispersed using a Solid Aerosol Generator (SAG 410; Topas GmbH, Germany). The ATD-containing sample flow was subsequently transmitted through a mixing chamber in order  
5 to reduce fluctuations in the aerosol concentrations resulting from variability in the output rate of the aerosol. A valve was used to direct the flow alternatingly through the PCVI or through a bypass, with each run lasting 30 s. The number size distributions of the particles thus transmitted were measured in the range of 0.5 - 20  $\mu\text{m}$  aerodynamic diameter using an Aerodynamic Particle Sizer (APS; model 3321, TSI, USA). The size distributions measured downstream of the PCVI were corrected for  
10 particle enrichment in the PCVI, which is given by a factor approximately equal to the ratio of the inlet flow to the outlet flow of the PCVI (Boulter et al., 2006). Finally, the transmission efficiency as a function of particle size was determined by taking the ratio of the enrichment-corrected size distribution downstream of the PCVI to the size distribution downstream of the bypass (see Fig. 1).

**Figure 1.** Particle concentration and transmission efficiency of the PCVI.
