1   **Abstract.** Measurements of mixing ratios and stable carbon isotope ratios of aromatic volatile

2   organic compounds (VOC) in the atmosphere were made in Toronto (Canada) in 2009 and 2010.

3   Consistent with the kinetic isotope effect for reactions of aromatic VOC with the OH-radical the

4   observed stable carbon isotope ratios are on average significantly heavier than the isotope ratios

5   of their emissions. The change of carbon isotope ratio between emission and observation is used

6   to determine the extent of photochemical processing (photochemical age, $\int[OH]dt$) of the

7   different VOC. It is found that $\int[OH]dt$ of different VOC depends strongly on the VOC

8   reactivity. This demonstrates that for this set of observations the assumption of a uniform

9    $\int[OH]dt$ for VOC with different reactivity is not justified and that the observed values for

10   $\int[OH]dt$ are the result of mixing of VOC from air masses with different values for $\int[OH]dt$.

11   Based on comparison between carbon isotope ratios and VOC concentration ratios it is also

12   found that varying influence of sources with different VOC emission ratios has a larger impact

13   on VOC concentration ratios than photochemical processing. It is concluded that for this data set

14   the use of VOC concentration ratios to determine $\int[OH]dt$ would result in values for $\int[OH]dt$

15   inconsistent with carbon isotope ratios and that the concept of a uniform $\int[OH]dt$ for an air mass

16   has to be replaced by the concept of individual values of an average $\int[OH]dt$ for VOC with

17   different reactivity.

18

19   **1. Introduction**

20   Anthropogenic volatile organic compounds (VOC) are important pollutants that play key

21   roles in the production of ozone, aerosol formation and significantly affect regional air quality in

22   general. Their total annual global emission is estimated at 150 TgC per year (Niedojadlo et al.,

23   2008; Piccot et al., 1992). On a global scale, about 60 to 80% of anthropogenic emissions are

1   associated with fossil fuel production, its distribution, use and storage, and up to 20 to 30% with

2   biomass burning (Reimann and Lewis, 2007; Rudolph et al., 2002). Since anthropogenic VOC

3   are rather diverse, classification of their emission sources is quite challenging, thus frequently

4   these emissions are grouped according to the commodities or activities with which they are

5   associated (Niedojadlo et al., 2008; Sawyer et al., 2000; Piccot et al., 1992; Watson et al., 1991),

6   for instance, vehicular exhaust, evaporated fuel, solvent use, etc. Aromatic VOC are an important

7   part of anthropogenic emissions (up to 44%), with benzene, toluene, ethylbenzene and xylenes as

8   major components (up to 75%) (Jang and Kamens, 2001).

9   In the atmosphere many VOC undergo chemical transformation via gas-phase reactions

10   with hydroxyl radicals (OH), nitrate radicals (NO_3), chlorine radicals (Cl) and ozone (O_3), with

11   OH contributing the most to these oxidation processes. This oxidative processing is especially

12   important for aromatic VOC and heavy alkanes, since it may result in the formation of

13   oxygenated and nitrated products that may contribute to the formation of secondary organic

14   matter (Saccon et al., 2015; Irei et al., 2006; Forstener et al., 1997).

15   It has been shown by many studies that the use of stable carbon isotope ratios is

16   beneficial in providing insights into photochemical transformation and physical processing of

17   ambient volatile organic compounds (Gensch et al., 2014; Rudolph, 2007; Stein and Rudolph,

18   2007; Ghosh and Brand, 2003; Goldstein and Shaw, 2003; Rudolph et al., 2003; Rudolph et al.,

19   2002; Meier-Augenstein, 1999). McKinney et al. (1950) introduced one of the first mass

20   spectrometers that were able to differentiate carbon and oxygen isotopologues in carbon dioxide

21   and oxygen molecules (Richet et al., 1977; McKinney et al., 1950). This development was

22   followed by extensive studies of the stable carbon isotope composition of carbon monoxide,

23   carbon dioxide and methane in ambient samples (Brenninkmeijer et al., 1995; Lowe et al., 1994;

3

1   Stevens et al., 1972) and theoretical modelling and interpretations began to be presented

2   (Brenninkmeijer et al., 1995; Kaye, 1987; Richet et al., 1977; Craig, 1953).

3   While some trace gases, such as methane, carbon monoxide, or carbon dioxide are

4   present in the atmosphere at μmol mol^{-1} or high nmol mol^{-1} levels and are easy to measure with

5   state of the art isotope ratio mass spectrometry, most VOC are present at mixing ratios that are 3

6   to 5 orders of magnitude lower than for methane or carbon monoxide, thus making the

7   measurement of their isotopic composition challenging. In 1997 a method which allowed the

8   determination of stable carbon isotope composition for ambient compounds present at low

9   mixing ratios was introduced (Rudolph et al., 1997). It was followed by isotope ratio

10   measurements of various VOC, where it was applied and expanded (Kornilova et al., 2015a;

11   Kornilova et al., 2015b; Kawashima and Murakami, 2014; Wintel et al., 2013; Vitzthum-von

12   Eckstaedt et al., 2012; Giebel et al., 2010; Redeker et al., 2007; Nara et al., 2006; Turner et al.,

13   2006; Komatsu et al., 2005; Czapiewski et al., 2002; Rudolph et al., 2002; Saito et al., 2002).

14   Still, the number of publications containing measurements of isotope ratios of ambient VOC and

15   their sources is very limited (Kornilova et al., 2015b; Gensch et al., 2014; Elsner et al., 2012).

16   The stable carbon isotope ratio is determined by the ratio of ^{13}C to ^{12}C atoms in the

17   sample and is usually expressed in delta notation ($\delta^{13}C$) relative to a reference value (Vienna

18   Peedee Belemnite, VPDB) with $^{13}C/^{12}C = 0.0112372$ (Craig, 1953)). Since changes in $^{13}C/^{12}C$

19   are small, $\delta^{13}C$ is expressed in parts per thousand (‰) (Eq. 1).

20

$$\delta^{13}C = \frac{R_{sample}(^{13}C/^{12}C) - R_{VPDB}(^{13}C/^{12}C)}{R_{VPDB}(^{13}C/^{12}C)} \times 1000‰ \qquad \text{Eq. 1}$$

21

4

1

2   The presence of ^{13}C isotopes slightly affects the reaction rate of the molecule, as ^{13}C containing

3   isotopologues react slower than ^{12}C-only isotopologues. The relative difference between these

4   rate constants ([12]k and [13]k), known as kinetic isotope effect (KIE), is expressed in epsilon

5   notation (ε) in parts per thousand (‰) (Eq. 2).

$$\varepsilon_{OH} = \frac{^{12}k - {}^{13}k}{^{13}k} \times 1000‰ \qquad \text{Eq. 2}$$

6

7   Since ^{12}C is more reactive, the sample gets enriched in ^{13}C with time and the magnitude of this

8   depends on the extent of processing as well as the KIE.

9   The term "photochemical age" is used for quantification of photochemical processing of

10   a compound and it is usually defined as the time integral of the OH concentration ($\int[OH]dt$).

11   Originally VOC concentration ratios were used to determine $\int[OH]dt$, an approach that often is

12   referred to as hydrocarbon clock (Kornilova et al., 2015b; Stein and Rudolph, 2007; Kleinman et

13   al., 2003; Rudolph et al., 2003; Thompson et al., 2003; Rudolph and Czuba, 2000; Jobson et al.,

14   1999; Jobson et al., 1998). This concept implies that $\int[OH]dt$ is identical for the VOC used for

15   the calculation and sometimes the term photochemical history of an air masses is used (Parrish et

16   al., 1992). The isotope hydrocarbon clock approach is similar, but uses stable carbon isotope

17   ratios (Rudolph and Czuba, 2000) (Eq. 3):

$$\int[OH]dt = \frac{\delta_A{}^{13}C - \delta_S{}^{13}C}{k_{OH}\varepsilon_{OH}} \qquad \text{Eq. 3}$$

18

1 where $\int[OH]dt$ is the average photochemical age, $\delta_A{}^{13}C$ and $\delta_S{}^{13}C$ are the stable carbon isotope

2 compositions of ambient and freshly emitted VOC respectively, k_{OH} is the rate constant for the

3 reaction of VOC and OH, and ε_{OH} is the KIE (Eq.2). Since this approach only uses one

4 compound for calculating $\int[OH]dt$ it is possible to determine an average value of $\int[OH]dt$ for

5 individual VOC.

6   In this paper we present stable carbon isotope ratios of ambient aromatic VOC measured

7 at a suburban area in 2009 and 2010. The results will be used to determine $\int[OH]dt$ for VOC with

8 different reactivity and to determine the impact of photochemical processing on the change in

9 VOC concentration ratios.

10

11 **2. Materials and method**

12   Selective VOC sampling from ambient air was done using cartridges (13 to 15 cm long,

13 1/4" OD) filled with Carboxene 569, a mass flow controller and a diaphragm pump with a

14 sampling flow rate set between 10 and 50 mL min^{-1} as described in detail by Kornilova et al.

15 (2015a). VOC were quantitatively extracted from cartridges using a thermal desorption unit with

16 helium as a carrier gas (60 to 80 mL min^{-1}) at 553 K for 40 min. Desorbed VOC were focused

17 using a two stage preconcentration system. Compounds were then separated using a HP5890

18 Series II gas chromatograph equipped with a DB-1 column (100 m, 0.25 mm ID, 0.5µm film

19 thickness). Separated compounds were directed to a combustion interface (1/4" OD, 0.5 mm ID,

20 44 cm long ceramic tube with copper, nickel and platinum wires inside) where they were

21 converted to H_2O and CO_2. H_2O was removed by Nafion tubing, while CO_2 was directed into an

22 Isotope Ratio Mass Spectrometer (IRMS) where m/z 44, 45 and 46 were analysed. Performance

23 characteristics of the sampling and analysis procedures discussed by Kornilova et al. (2015a) are

6

1 summarized in Table 1. The accuracy of $\delta^{13}C$ measurements was 0.5 ‰ for sample masses

2 exceeding 3 ng of the target compound. For a typical 24h sample this mass corresponds to an

3 atmospheric mixing ratio of 20 to 30 pmol mol^{-1}. $\delta^{13}C$ results are not reported here for sample

4 masses that were lower than this.

5 　　　Ambient VOC were collected at a site located in the Northern part of the Greater Toronto

6 Area (GTA) on the premises of the Downsview location of Environment Canada (43°46′N,

7 79°28′W) from 2009 to 2010 (Fig. 1). Samples were collected from Monday to Thursday over 24

8 h time periods (7 to 7 AM), Friday sampling lasted 6 to8 h (7 AM to 4 PM) and Friday to Sunday

9 samples were collected over 64 h (4 PM on Friday to 7 AM on Monday). Most samples were

10 collected between Fall 2009 and Winter 2010 (October 2009 to February 2010), with some

11 additional samples collected in March 2010, and from August 2010 to September 2010. The

12 average sampling flow rate was 24 to 25 mL min^{-1}. In total, 74 samples were analysed for VOC

13 concentrations and carbon isotope ratios, although in several of those samples carbon isotope

14 ratios could only be determined for some of the target compounds.

15

16 **3. Results and discussion**

17 **3.1 Overview**

18 　　　Averages and some basic statistics for concentrations of ambient aromatic VOC collected

19 in Toronto (2009 to 2010) are summarized in Table 2. Mixing ratios determined for the targeted

20 VOC are in the low to mid pmol mol^{-1} range and are similar to mixing ratios reported by

21 Canada's National Air Pollution Surveillance Program (NAPS, 2009-2010) for downtown

22 Toronto and two suburban locations in Toronto (Table 3). The observed mixing ratios are also

23 within the range of values reported in several measurement series at various locations in North

1   America (Kornilova et al., 2015b; Jobson et al., 2004; Pankow et al., 2003; Riemer et al., 1998;

2   Hagerman et al., 1997; Roberts et al., 1984).

3   Except for benzene, the VOC mixing ratios are linearly correlated with each other with y-

4   axis intercepts close to zero. Except for the linear correlation between the mixing ratios of

5   ethylbenzene and o-xylene, the y-axis intercept is statistically not different from zero (95%

6   confidence interval) (Table 4, Fig. 2). The VOC concentration ratios observed are within or close

7   to the range of values reported in literature. Exceptions are the toluene over benzene ratio and the

8   p,m-xylene over o-xylene ratio, which are higher than previously reported ratios (Table 5) but

9   similar to the ratios that can be derived from the NAPS data reported for other locations in

10   Toronto in Table 3.

11   Averages and basic statistics for measured carbon isotope ratios are summarized in Table

12   6. The majority of the determined $\delta^{13}C$ values are comparable with those observed in other

13   ambient studies (Table 7). The only exception is the value reported by Redeker et al. (2007) for

14   benzene, which is about 3 ‰ lighter than the average for our measurements, and close to the 10th

15   percentile of our observations.

16   Figure 3 shows the frequency distribution for the measured carbon isotope ratios. The

17   lower end of the distribution is close to the carbon isotope ratios reported in literature for their

18   emissions (Table 8). The only exception are the benzene and toluene carbon isotope ratios

19   reported by Turner et al. (2006) for industrial stack emissions which are about 3 to 5 ‰ heavier

20   than the lower end of our observations. Turner et al. (2006) reported no details of the type of

21   industrial emissions studied and therefore the possible impact of such heavier industrial

22   emissions on ambient carbon isotope ratios cannot be evaluated. Only 13 of our 275 measured

23   carbon isotope ratios are significantly below the carbon isotope ratios reported by Rudolph et al.

8

1   (2002) for emissions in Toronto, whereas 186 observations are significantly heavier (95 %

2   confidence limit determined from the uncertainty of the emission ratios and measurement errors).

3   Overall, there is little systematic change of the carbon isotope ratios with season (Fig. 3).

4   The only significant exceptions are the carbon isotope ratios of the C_2-alkylbenzenes, which are

5   approximately 2 ‰ lighter in spring and fall compared to summer and winter (T-test, 99.9%

6   probability).

7   There is a strong dependence between carbon isotope ratios of ethylbenzene and o-

8   xylene, ethylbenzene and p,m-xylene as well as o-xylene and p,m-xylene. The correlations

9   between the carbon isotope ratio of toluene and the C_2-alkylbenzenes are only weak and no

10   correlation between the carbon isotope ratios of benzene and any of the other aromatic VOC is

11   found (Fig. 4, Table 9). None of the y-axis intercepts of the linear regressions are significantly

12   different from zero (95 % confidence interval), which is consistent with the finding that the

13   carbon isotope ratios of emissions for different aromatic VOC are similar (Rudolph et al., 2002).

14   There is no clear dependence between mixing ratios and carbon isotope ratios (Fig. 5), although

15   in some cases the mixing ratios on average differed for different ranges of carbon isotope ratios

16   (see below).

17

18   **3.2 Ambient carbon isotope ratios and atmospheric VOC processing**

19   The observed carbon isotope ratios cover a range of more than 8 ‰ (Fig. 3), which

20   cannot be explained by measurement errors (Table 1) or uncertainty of the carbon isotope ratios

21   of known VOC sources (Table 8). Although the existence of unidentified sources of VOC with

22   very heavy carbon isotope ratios cannot be completely ruled out, it is unlikely that this could

23   explain the observed variability of measured carbon isotope ratios since such an unidentified

1   source would have to be of approximately the same magnitude as the known sources to explain

2   the absence of a systematic dependence between VOC carbon isotope ratio and VOC mixing

3   ratios (Fig. 5).

4   Anderson et al. (2004) reported that the reaction of aromatic VOC with the OH-radical,

5   which is the dominant loss process for light aromatic VOC in the atmosphere, results in

6   enrichment of ^{13}C in the residual VOC. Variations in the extent of reaction with OH-radicals can

7   therefore explain the observed variability of carbon isotope ratios as well as the absence of a

8   significant number of δ^{13}C values lower than the δ^{13}C values of emissions (Table 8). Table 10

9   summarizes the rate constants and KIEs for the reaction of the studied compounds with the OH-

10   radical as well as the δ^{13}C values reported for their emissions in Toronto by Rudolph et al.

11   (2002). Included in Table 10 are also the δ^{13}C values calculated from $\delta^{13}C_{steady\ state} = \delta^{13}C_{emissions}$

12   $+\epsilon_{OH.}$ Here $\delta^{13}C_{steady\ state}$ is the hypothetical average carbon isotope ratio of an atmospheric VOC

13   in steady state between emissions and loss by reaction with the OH-radical. For comparison the

14   average of measured δ^{13}C values is also given in Table 11.

15   The averages of the measured δ^{13}C values are consistently lighter than the predictions for

16   steady state. However, only for toluene and benzene, the least reactive of the light aromatic

17   VOC, this difference is statistically significant at the 99% confidence level. Since the

18   measurements were made at a location impacted by substantial emissions within a less than 10

19   km radius it is not surprising that for VOC with a short atmospheric residence time the average

20   carbon isotope ratio is closer to a steady state between emission and removal reaction than for

21   less reactive VOC. Indeed, the Pearson product moment correlation coefficient for the difference

22   between steady state and average measured isotope ratios and atmospheric residence time is

1   0.863 and the R^2 for a linear correlation is 0.745. However, this is only based on data for 5

2   different compounds and the average of the carbon isotope ratios is the result of isotope ratio

3   measurements covering a wide range of $\delta^{13}C$ values (Fig. 3).

4   Table 11 shows a breakdown of measured $\delta^{13}C$ values into different ranges by

5   compound. The number of observations with $\delta^{13}C$ values heavier than steady state between

6   emission and removal is in the range of 25 % for the C_2-alkylbenzenes whereas for toluene less

7   than 10 % of the observations fall into this range. For benzene, the by far least reactive of the

8   studied VOC, the percentage of data points close to steady state $\delta^{13}C$ values is even smaller.

9   There is no systematic dependence between the percentages of $\delta^{13}C$ values close to the source

10   isotope ratios and VOC reactivity. This is compatible with the concept that photochemical aging

11   is an important process resulting in changes in the carbon isotope ratios of ambient VOC as well

12   as the predicted dependence between carbon isotope ratio and the rate constant for the

13   atmospheric VOC removal reactions (Equation 3).

14   In principle these findings are similar to the change in VOC concentration ratios as result

15   of photochemical processing, which has been used to study and quantify photochemical VOC

16   processing in the atmosphere (Kleinman et al., 2003; Jobson et al., 1999; Jobson et al., 1998;

17   Parrish et al., 1992; Rudolph and Johnen, 1990). It has been shown that the $\int[OH]dt$ determined

18   from $\delta^{13}C$ values of VOC is a valid approximation for the age of the studied VOC even in the

19   case of mixing air masses with different values for $\int[OH]dt$ (Rudolph and Czuba, 2000), whereas

20   the use of VOC concentration ratios to quantify VOC processing requires an identical $\int[OH]dt$

21   for VOC with different reactivity (Rudolph and Johnen, 1990), a condition that often is referred

22   to as photochemical age of the air mass (Parrish et al., 1992). The validity of the assumption of

1   an identical ∫[OH]*dt* for VOC of different reactivity can be tested by a comparison of carbon

2   isotope ratios predicted by Equation 3 for identical ∫[OH]*dt*:

3

4
$$\frac{\delta_A^{A\,13}C - \delta_S^{A\,13}C}{\delta_A^{B\,13}C - \delta_S^{B\,13}C} = \frac{k_{OH}^A \varepsilon_{OH}^A}{k_{OH}^B \varepsilon_{OH}^B}$$
Eq. 4

5   In Table 12 the slopes calculated for identical values for the average ∫[OH]*dt* of different

6   VOC are compared with the slopes determined from linear regression of measured carbon

7   isotope ratios. With the exception of the dependence between toluene and ethylbenzene, which

8   have similar reactivity towards the OH-radical, the calculated slopes differ substantially from the

9   observed slopes demonstrating that the assumption of an identical ∫[OH]*dt* for VOC with

10   different reactivity is not valid. This strongly points towards mixing air masses containing VOC

11   with different values for ∫[OH]*dt*. This is consistent with the location of the sampling site at the

12   outskirts of a major city and a sampling duration that lasted at least several hours, in most cases

13   about one day.

14

15   **3.3 Photochemical age and mixing of air masses**

16   Carbon isotope ratios of VOC allow calculation of the average ∫[OH]*dt* of the individual

17   volatile organic compound without the requirement of a uniform ∫[OH]*dt* and therefore our

18   observations can be used to determine the ∫[OH]*dt* of VOC with different atmospheric life time

19   independent of assumptions about atmospheric mixing. Table 13 lists basic statistics for the

20   values of ∫[OH]*dt* determined from our $\delta^{13}C$ measurements based on Equation 3 using the kinetic

21   data and carbon isotope ratios of VOC emissions listed in Table 10.

1   Due to the uncertainty of the carbon isotope ratios of emissions and measurement errors

2   low values of ∫[OH]dt have large relative uncertainty. The consequence is a substantial number

3   of negative ∫[OH]dt values. Nevertheless, out of the 275 ∫[OH]dt values only 13 are below zero

4   at a 95 % confidence limit determined from the uncertainty of the ∫[OH]dt whereas 166 of the

5   ∫[OH]dt values are significantly larger than zero (95% confidence limit).

6   The values for average ∫[OH]dt of the different VOC differ substantially. The highest

7   average ∫[OH]dt of 3.1×10^{11} s molecules cm^{-3} is found for benzene, whereas the average ∫[OH]dt

8   for the most reactive VOCs is only 3.4×10^{10} s molecules cm^{-3} (Table 13). There is strong

9   evidence for a systematic dependence between atmospheric residence time and average ∫[OH]dt

10   (Fig. 6). The Pearson product moment correlation coefficient for the dependence between

11   ∫[OH]dt and atmospheric residence time is 0.981 and R^2 for a linear fit is 0.963. The correlation

12   is strongly influenced by the data point for the benzene. When excluding this data point the

13   Pearson product moment correlation coefficient is 0.760 and R^2 for a linear fit is 0.578. The

14   finding of differences in ∫[OH]dt for VOC with different reactivity is similar to the results of a

15   comparison of the ages of ethane and n-butane derived from carbon isotope ratios reported by

16   Saito et al. (2002) for the western North Pacific. They report that the age of ethane in most cases

17   is approximately an order of magnitude larger than the age of n-butane, which is similar to the

18   ∫[OH]dt -reactivity dependence in Figure 6, although the range of VOC reactivity covered in this

19   paper does not include the low reactivity of ethane.

20   The dependence of the ∫[OH]dt on VOC reactivity is also seen for individual samples. In

21   Figure 7 the ∫[OH]dt of different VOC are compared with ∫[OH]dt determined for p,m-xylene,

22   the most reactive VOC. Since the ∫[OH]dt is a linear function of the carbon isotope ratios

23   (Equation 3) it is not surprising that the comparison showed strong correlations between the

13

1   values for $\int$[OH]dt of the C$_2$-alkylbenzenes and no significant linear correlation between the

2    $\int$[OH]dt of benzene and $\int$[OH]dt of p,m-xylene. With the exception of 4 data points for $\int$[OH]dt

3   of toluene the values for $\int$[OH]dt of less reactive VOC were consistently higher than those for

4   p,m-xylene, the most reactive of the studied VOC.

5   The systematic dependence of $\int$[OH]dt on VOC reactivity can be explained by mixing of

6   air masses that have been subject to different extents of photochemical processing. During

7   photochemical aging VOC of high reactivity will be removed at a faster rate than VOC of low

8   reactivity. Consequently the relative contribution to VOC of low reactivity compared to VOC of

9   high reactivity increases with increased photochemical processing and mixing of air masses that

10   have been subject to different degrees of photochemical processing will result in average $\int$[OH]dt

11   values that decrease with increasing VOC reactivity.

12

13   **3.4 Photochemical age and VOC concentration ratios**

14   For VOC with identical $\int$[OH]dt the change in concentration ratios can be predicted from

15   $\int$[OH]dt (Kleinman et al., 2003; Parrish et al., 1992; Rudolph and Johnen, 1990) as long as their

16   emission ratios are similar. In case of mixing of air masses with different $\int$[OH]dt, the change in

17   VOC concentration ratios depends on the relative contributions from the different air masses and

18   therefore is difficult to predict. The possibility to derive $\int$[OH]dt for VOC from their carbon

19   isotope ratios allows studying the dependence between VOC ratios and $\int$[OH]dt of the individual

20   compound. The only condition for this is a narrow range of carbon isotope ratios for the

21   emissions of the studied VOC.

22   Figure 8 shows some examples for the dependence between VOC concentration ratios

23   and $\int$[OH]dt of o-xylene and toluene. The ratios exhibit substantial scatter, especially for ratios

14

1   relative to benzene or toluene. Overall there is no clear dependence between $\int[OH]dt$ and VOC

2   ratios. For many VOC pairs the ratios show substantial deviations from the dependence between

3   $\int[OH]dt$ and concentration ratios predicted for identical values for average $\int[OH]dt$. However, for

4   VOC pairs with similar reactivity or low reactivity for both VOC prediction and observation

5   agree. This suggests that, similar to the dependence between VOC concentrations and carbon

6   isotope ratios (Fig. 5) mixing of air masses with different VOC concentration ratios plays a

7   major role in determining VOC ratios.

8   A change in VOC concentration ratios may be caused by varying impact from emission

9   sources with different emission ratios or different $\int[OH]dt$. With increasing photochemical age

10 the concentrations of a more reactive VOC will decrease faster than the concentration of a less

11 reactive VOC. In case of mixing air masses containing VOC with different $\int[OH]dt$ the relation

12 predicted by the hydrocarbon clock concept is no longer applicable, but qualitatively the ratios

13 for concentrations of more reactive VOC over those of less reactive VOC will still decrease with

14 increasing $\int[OH]dt$.

15   Figure 9 shows the relative change in the ratios for the concentration of different VOC

16 over the concentration of benzene averaged for 4 intervals of $\int[OH]dt$ derived from the p,m-

17 xylene carbon isotope ratio. Also shown is the relative change in $\int[OH]dt$ of benzene for the

18 same intervals. Although the averages have substantial uncertainties, there is evidence for a

19 systematic dependence. For the C_2 alkyl benzenes the difference between the lowest and highest

20 ratios is significant at the 90% confidence level (T-test). Furthermore, it is unlikely that the

21 observation of similar trends for all ratios is a coincidence. Most importantly, the observations

22 are incompatible with the expected change of VOC concentration ratios with increasing $\int[OH]dt$.

1   Benzene is the by far least reactive of these VOC; consequently photochemical processing is

2   expected to decrease the alkylbenzene over benzene concentration ratios, which is not observed.

3   Figure 10 shows the relative difference between the averages for all VOC concentration

4   ratios and the average concentration ratios for VOC without significant depletion of ^{13}C relative

5   to the isotope ratio of emissions. The separation between these two groups is based on the 95%

6   confidence limit calculated from measurement error and uncertainty of δ^{13}C of emissions (Table

7   10). For comparison the change in ratios predicted from the average $\int[OH]dt$ of the VOC in

8   Table 13 is included in Figure 10. For C_2-alkylbenzenes the predicted and observed changes in

9   concentration ratios agree within their uncertainties, although for the o-xylene over ethylbenzene

10 concentration ratio the high uncertainty does not allow a meaningful comparison. However,

11 VOC concentration ratios relative to benzene or toluene show a substantial difference between

12 prediction and observation. Moreover, for concentration ratios relative to benzene the samples

13 with negligible photochemical processing have ratios lower than the average, which can only be

14 explained by impact of sources with different VOC emission ratios. Specifically, it can be

15 concluded that sources directly impacting the sampling location on average have lower emission

16 ratios relative to benzene than emissions from sources located at a distance allowing for

17 photochemical aging of the VOC. This demonstrates that in this case the differences in emission

18 ratios are larger than the impact of photochemical aging.

19   Based on the location of the sampling site, traffic related emissions are expected to have a

20 major impact on VOC concentrations. Other potentially important sources are emissions from

21 industrial facilities. In Table 14 VOC emission ratios for transportation related emissions from

22 literature and industrial facilities in Ontario and the Toronto region reported by the National

23 Pollutant Release Inventory (NPRI) are compared with the average ratios for our measurements.

16

1   Although VOC concentration ratios in vehicular emissions cover a range of nearly a factor of 2,

2   the observed average ratios relative to benzene are consistently at the upper end or above this

3   range but close to emission ratios for industrial facilities in Ontario. Since emission ratios

4   relative to benzene for industrial facilities in the Toronto area are much higher than the average

5   for Ontario (Table 14) differences in emission ratios from industrial facilities between Toronto

6   and the rest of Ontario can be ruled out as explanation for the lower concentration ratios relative

7   to benzene for samples with little photochemical processing. In contrast to the concentration

8   ratios relative to benzene, due to the similarity in emission ratios for industrial facilities and

9   traffic (Table 14) and the possible change of these ratios due to photochemical processing, it is

10 difficult to extract information about contributions from these two source types from

11 concentration ratios for alkyl benzenes without additional information.

12   Most of the major sources of light aromatic VOC in Ontario are located Southwest and

13 West of the sampling site (Fig. 11). Therefore insight into the impact of emissions from

14 industrial facilities on concentration ratios and carbon isotope ratios can be gained by filtering

15 the samples based on predominant wind direction during sampling. In Table 15 the average VOC

16 carbon isotope ratios for the two wind sectors are compared. With the exception of toluene the

17 average carbon isotope ratios for samples collected under the influence of airflow from North or

18 East are heavier than in samples with wind from the South or West sectors. For benzene this

19 difference is statistically significant at the 98% level (T-test) and for the C2-benzenes at a >90%

20 level. This is consistent with the existence of larger sources of aromatic VOC in the S+W sector

21 compared to the N+E sector (Fig. 11). The absence of a statistically significant difference in

22 isotope ratios for toluene is most likely due to the existence of a nearby major industrial source

23 of toluene east of the sampling site (Fig. 12).

1   Based on the difference in carbon isotope ratios between samples for the two wind

2   sectors it is expected that there also will be differences in concentration ratios. In Table 15

3   average VOC concentration ratios for samples dominated by southerly or westerly airflow are

4   compared with ratios for samples with winds from either North or East. For ratios relative to

5   benzene substantial differences between the two wind sectors are found. For the C_2-

6   alkylbenzenes the difference is statistically significant at >95 % (T-test), for toluene at the 89 %

7   level. However, for concentration ratios between alkylbenzenes no statistically significant

8   differences can be seen. The lower concentration ratios relative to benzene in the N+E samples

9   can therefore be explained either by impact of aged air which is, relative to benzene, depleted in

10   the more reactive alkyl benzenes due to photochemical processing or lower emissions of

11   alkylbenzenes from industrial facilities in the N+E sector.

12   VOC carbon isotope ratios can be used to test which of these two factors dominates.

13   Using the carbon isotope ratio of p,m-xylene the N+E sector samples are separated into two

14   groups of samples with different values for $\int[OH]dt$. The separation into two groups is based on

15    $\int[OH]dt$ of p,m-xylene being larger than zero at the 99% confidence limit. The confidence limit

16   was calculated from the uncertainty of the isotope ratio of emissions, the measurement

17   uncertainty and the uncertainty of the KIE. This $\int[OH]dt$ is 3×10^{10} OH-radicals cm^{-3} s, which

18   corresponds to approximately 8 h for an average OH radical concentration of 10^6 cm^{-3}. The

19   average concentration ratios for these two groups are included in Table 15. The average $\int[OH]dt$

20   of p,m-xylene for samples dominated by recent emissions of p,m-xylene is 2.3×10^9 OH-radicals

21   cm^{-3} s corresponding to 0.6 hours for an average OH radical concentration of 10^6 cm^{-3}. However,

22   it should be noted that, due to the uncertainty in the isotope ratio of p,m-xylene emissions this

23   average value has an uncertainty of approximately 1.3×10^{10} OH-radicals cm^{-3} s corresponding to

18

1   nearly 4 hours for an average OH radical concentration of 10^6 cm^{-3}. For samples dominated by

2   aged p,m-xylene the average ∫[OH]dt is 7.4x10^{10} OH-radicals cm^{-3} s corresponding to 21 h for an

3   average OH radical concentration of 10^6 cm^{-3}.

4   In contrast to the expected decrease in the concentration ratios for more reactive VOC

5   over less reactive VOC with increasing ∫[OH]dt, the average ratios are always higher for the aged

6   samples. Although the difference is statistically significant at a > 90 % level for only 6 of the

7   concentration ratios, this finding rules out photochemical processing as main reason for the

8   observed changes in VOC concentration ratios. For this set of observations differences in

9   ∫[OH]dt derived from carbon isotope ratios most likely reflect differences in the footprint area

10   that impacts VOC concentration ratios. Samples with low values for ∫[OH]dt represent the

11   impact of nearby sources, most likely traffic related emissions, consistent with concentration

12   ratios that are close to the typical traffic dominated VOC ratios (Table 14).

13   The concentration ratio of p,m-xylene over ethylbenzene has been used as an indicator of

14   photochemical processing (Miller et al., 2012; Monod, 2001). It has been reported that the ratio

15   of p,m-xylene to ethylbenzene emissions is nearly constant for different sources (i.e. exhaust,

16   petrochemical activities, solvent use, etc.) and varies from 3.5 to 4.0 (Nelson and Quigley, 1983).

17   Since photochemical removal is approximately 3 times faster for p,m-xylene than for

18   ethylbenzene (Table 6), it has been suggested that any value of this ratio lower than 3.5 is a good

19   indicator of photochemical ageing (Nelson and Quigley, 1983; Miller et al., 2012; Monod, 2001;

20   Civan et al., 2015). This is in contrast to the higher concentration ratio of p,m-xylene to

21   ethylbenzene observed in samples with photo-chemically aged p,m-xylene for the N+E sector

22   compared to samples dominated by recent emission of p,m-xylene (Table 15). Although the

23   observed relative increase in concentration ratios of 50% has an uncertainty of 40% and is

19

1 statistically not significant (T-test), it is inconsistent with the decrease by approximately 60%

2 which is expected from the difference in the average $\int[OH]dt$ for these two data sets. This can be

3 explained by the difference in xylene over ethylbenzene emission ratios between traffic related

4 emissions and industrial facility emissions (Table 14). Samples with low values for the average

5 $\int[OH]dt$ for p,m-xylene will be dominated by emissions from nearby sources, most likely traffic,

6 while for samples with higher $\int[OH]dt$ for p,m-xylene the footprint area will be much larger and

7 industrial emissions will play a more significant role.

8

9 **4. Conclusions**

10   Measurement of carbon isotope ratios of ambient VOC can be used to obtain detailed

11 insight into origin and sources of VOC. This is especially important in cases where different

12 source types impact ambient VOC levels and the source location alone does not allow identifying

13 the dominant source type. In such cases the use of VOC concentration ratios can result in

14 incorrect estimates of photochemical processing. Moreover, the comparison of $\int[OH]dt$ derived

15 from carbon isotope ratios of VOC demonstrates that in the case of mixing of air masses with

16 differences in $\int[OH]dt$ the average $\int[OH]dt$ for VOC with different reactivity differ. Typically

17 $\int[OH]dt$ for more reactive VOC will be lower than $\int[OH]dt$ for less reactive VOC. It can

18 therefore be concluded that in this study the assumption of a uniform $\int[OH]dt$ for different VOC

19 is not justified and consequently the use of VOC concentration ratios to determine $\int[OH]dt$

20 would give incorrect results.

21   The use of carbon isotope ratios or $\int[OH]dt$ derived from carbon isotope ratios allows

22 differentiation between samples impacted by emissions from different footprint areas. The

23 comparison of carbon isotope ratios and VOC concentration ratios demonstrates that in this study

1 differences in the emission ratios for different types of VOC sources have a larger impact on

2 ambient VOC concentration ratios than photochemical aging.

3 For the VOC studied here reaction with the OH-radical is the only relevant loss process

4 in the atmosphere. Although the OH-radical concentration exhibits significant seasonal, diurnal

5 and spatial variability, $\int[OH]dt$ derived from isotope ratios also depends on the time between

6 emission of the VOC and observation. Consequently $\int[OH]dt$ also contains information on the

7 footprint area which impacts the observation site. VOC have widely different photochemical

8 reactivity; the reactivity of VOC used in our study cover a range of a factor of nearly 20. Values

9 for average $\int[OH]dt$ derived from carbon isotope ratios cover the range from effectively zero to

10 approximately 8×10^{11} OH-radicals cm^{-3} s corresponding to 9 days for an average OH radical

11 concentration of 10^6 cm^{-3}. The lower end of useful values for $\int[OH]dt$ that can be determined

12 from VOC carbon isotope ratios strongly depends on the uncertainty of the carbon isotope ratio

13 of emissions. Due to the limited number of studies of carbon isotope ratios of VOC emissions,

14 this substantially contributes to uncertainty in isotope ratio derived $\int[OH]dt$. For the most

15 reactive VOC used in this study the uncertainty in $\int[OH]dt$ resulting from uncertainty in the

16 carbon isotope ratio of emissions corresponds to 4 h at an average OH radical concentration of

17 10^6 cm^{-3}. The uncertainty in $\int[OH]dt$ of p,m-xylene due to carbon isotope ratio measurement

18 errors corresponds to less than 1.5 h. Therefore more detailed understanding of the carbon

19 isotope ratio of VOC emissions will reduce the lower end of meaningful values for $\int[OH]dt$ that

20 can be determined from carbon isotope ratios of atmospheric VOC.

21 In this study sampling periods of at least several hours, in most cases of one day were

22 used. This is useful for determining meaningful averages from a limited set of measurements,

23 However, this does not allow differentiating between changes of $\int[OH]dt$ with time during the

21

sampling period and mixing oVOC with different $\int[OH]dt$ in the atmosphere prior to sampling.

Separating the impact of the two processes on the VOC isotope ratio would require VOC isotope

ratio measurements in samples collected during short time periods of only a few minutes or less.

To our knowledge no such VOC isotope ratio measurements in an urban environment have been

published.

The finding of a dependence between average $\int[OH]dt$ and VOC reactivity is similar to

the finding of a substantial difference in $\int[OH]dt$ between ethane and n-butane in a marine

environment (Saito et al., 2002) as well as global modelling studies (Thompson et al., 2003;

Stein and Rudolph, 2007). However, to our knowledge, apart from this study no data that would

allow systematic study of the relation between VOC concentration ratios and carbon isotope

ratios in urban areas have been published. It can therefore not be decided to which extent the

observed discrepancy between $\int[OH]dt$ derived from carbon isotope ratios and changes in VOC

concentration ratios is a general problem for determining $\int[OH]dt$ from VOC concentration ratios

or limited to conditions specific for this or similar data sets.

6

Table 1. Performance of the system for analysis of volatile organic compounds in ambient air.

Compound	Detection Limit[a] (ng)	Relative precision in concentration measurement[b] (%)	Precision in $\delta^{13}C$ measurement[c] (‰)
Benzene	1.5	4	0.3
Toluene	0.4	4	0.2
Ethylbenzene	0.6	6	0.2
o-Xylene	0.4	8	0.3
p,m-Xylene	0.5	9	0.3

[a] Detection limit calculated using 3σ, where σ is the standard deviation of blank values determined from 3-4 repeat measurements.
[b] Precision calculated as relative standard deviation (%) of peak area for >10 repeat measurements.
[c] Precision calculated as standard deviation of $\delta^{13}C$ values for >10 repeat measurements.

Table 2. Mixing ratios (nmol mol^{-1}) determined for volatile organic compounds collected in Toronto (2009-2010).

Compound	N[a]	Mean	s[b]	Median	Minimum	Maximum	90th percentile	10th percentile
Benzene	65	0.13	0.12	0.11	0.02	0.74	0.28	0.03
Toluene	73	0.64	0.44	0.56	0.05	2.11	1.39	0.16
Ethylbenzene	69	0.07	0.05	0.05	0.01	0.26	0.14	0.02
o-Xylene	66	0.05	0.03	0.04	0.01	0.17	0.10	0.01
p,m-Xylene	68	0.17	0.13	0.14	0.01	0.74	0.36	0.04

[a] Number of measurements.
[b] Sample standard deviation.

Table 3. Average mixing ratios (nmol mol^{-1}) calculated from data reported by the National Air Pollution Surveillance Program (NAPS) for three locations in Toronto during the time periods covered in this work.

Location	Etobicoke West[a]		Downtown Toronto[b]		Etobicoke South[c]		This work	
Compound	mean	s[d]	mean	s[d]	mean	s[d]	mean	s[d]
Benzene	0.18	0.07	0.23	0.10	0.20	0.10	0.13	0.12
Toluene	0.49	0.31	0.62	0.55	0.68	0.65	0.64	0.44
Ethylbenzene	0.06	0.04	0.07	0.04	0.09	0.06	0.07	0.05
o-Xylene	0.05	0.04	0.07	0.04	0.07	0.05	0.05	0.03
p,m-Xylene	0.18	0.13	0.23	0.13	0.27	0.21	0.17	0.13

[a] Elmcrest Road, Toronto, ON, Canada.
[b] 223 College S., Toronto, ON, Canada.
[c] 461 Kipling Ave., Toronto, ON, Canada.
[d] Sample standard deviation.

1 **Table 4.** Linear regression analysis of mixing ratio correlations. Values above the diagonal are
2 R^2 and below are the intercepts[a].

	Benzene[b]	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
Benzene[b]		<0.3	<0.3	<0.3	<0.3
Toluene	NA		0.495	0.586	0.488
Ethylbenzene	NA	0.011 (0.008)		0.825	0.964
o-Xylene	NA	0.003 (0.006)	0.008 (0.003)		0.877
p,m-Xylene	NA	0.020 (0.023)	-0.007 (0.005)	-0.014 (0.011)	

3 [a] Standard error of intercept (nmol mol^{-1}) in parenthesis. The values are for linear fits of the
4 mixing ratio of the more reactive VOC versus the mixing ratio of the less reactive VOC.
5 [b] No significant correlation was found for linear regressions of the mixing ratios of any of the
6 VOC versus the mixing ratios of benzene.
7
8 **Table 5.** Ratios of VOC mixing ratios. Values below the diagonal are the ratios for the
9 measurements presented in this work[a], values above the diagonal give the range of ratios
10 observed in literature[b].

	Benzene	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
Benzene		1.5-3.7	0.11-1.2	0.23-3.2	0.46-0.3.8
Toluene	6.6 (0.6)		0.07-0.35	0.14-0.86	0.27-1.1
Ethylbenzene	0.69 (0.08)	0.080 (0.01)		0.6-2.1	1.2-4.3
o-Xylene	0.52 (0.07)	0.069 (0.007)	0.64 (0.04)		1.7-2.9
p,m-Xylene	1.8 (0.2)	0.22 (0.003)	2.7 (0.07)	3.7 (0.2)	

11 [a] Standard error of ratios in parenthesis. The ratios are for the mixing ratio of the more reactive
12 VOC over the mixing ratio of the less reactive VOC. For compounds with correlated mixing
13 ratios the slope of the linear regressions and standard errors of the slopes is given, in the absence
14 of correlation the average of the ratios and standard error of average ratios is given.
15 [b] Range of observations in urban, residential and commercial areas reported by Hoque et al.,
16 (2008), Karl et al. (2009), Miller et al. (2011), Alghamdi et al. (2014), de Gennaro et al. (2015)
17 and Rad et al. (2014).
18
19 **Table 6.** Stable carbon isotope composition ($\delta^{13}C$, ‰) of ambient VOC collected in Toronto
20 (2009-2010).

Compound	N[a]	Mean	s[b]	Median	Range	10th percentile	90th percentile
Benzene	44	-25.0	3.4	-26.0	-39.4 to -13.6	-28.4	-20.9
Toluene	73	-24.8	3.2	-25.7	-28.5 to -7.7	-27.4	-20.5
Ethylbenzene	58	-24.0	4.0	-23.4	-34.8 to -17.4	-28.5	-18.8
o-Xylene	44	-23.3	3.5	-23.3	-30 to -16.5	-28.0	-18.4
p,m-Xylene	56	-24.0	4.1	-23.8	-34.6 to -16.4	-28.4	-18.9

21 [a] Number of measurements.
22 [b] Sample standard deviation.
23

24

1 **Table 7.** Average and standard deviation of reported stable carbon isotope composition measurements ($\delta^{13}C$, ‰) of ambient light
2 aromatic VOC[a].

Location	Benzene	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
Toronto[b]	-24.6 (2.3)	-25.0 (1.1)	-25.3 (2.7)	-24.9 (1.5)	-25.6 (1.0)
Belfast[c]	-23.8 (2.5)	-26.9 (0.9)	-26.5 (1.4)	-26.3 (1.3)	-27.4 (1.7)
Crossgar and Hillsborough[d]	-28.3 (1.7)				
South-west Germany[e]		-27 to -23			
Egbert[f]	-25.3 (2.6)	-24.8 (1.7)	-23.7 (3.6)	-23.4 (2.6)	-23.8 (3.0)
Yurihonjo[g] (Japan)			-29.6 to -23.5		

3 [a] Sample standard deviation is given in parenthesis.
4 [b] Urban Canada (Rudolph et al., 2002).
5 [c] Urban Northern Ireland (Redeker et al., 2007).
6 [d] Rural Northern Ireland (Redeker et al., 2007).
7 [e] Vertical profile over rural area, only range of data available (Wintel et al, 2013).
8 [f] Rural Canada (Kornilova et al., 2015b).
9 g Urban Japan, only range of data available (Kawashima and Murakami, 2014).
10
11

Table 8. Average stable carbon isotope ratios ($\delta^{13}C$, ‰) of major sources of ambient VOC. The sample standard deviation is given in parenthesis.

Source	Benzene	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
Gasoline[a]	-27.0 (-24.5 to-29.9)[b]	-26.0,-28.1[b]	-27.4 (2.8)	-26.5 (1.9)	-27.9 (1.2)
Tunnel[c]	-26.5 (1.0)	-27.5 (1.0)	-27.4 (0.9)	-27.3 (0.4)	-26.9 (2.0)
Gas Station[c]	-29.1 (0.3)	-27.4 (0.6)	-28.2 (0.4)	-27.1 (0.6)	-27.7 (0.5)
Gas Station[d]	-27.35 (1.6)	-27.08 (0.7)	-26.48 (1.6)		-27.4 (0.8)
Underground garage[c]	-27.7 (0.7)	-27.1 (0.7)	-27.5 (1.1)	-27.2 (1.1)	-27.7 (1.0)
Biomass burning[e]	-26.0 (0.1)	-26.5 (0.9)	-25.7 (0.5)		
Biomass burning[f]	-27.6 (1.6)	-27.1 (1.3)			
Fossil fuel combustion[f]	-26.9 (0.3)	-27.5 (0.6)			
Industrial stack[g]	-23.5 (0.11)	-25.4 (0.48)			

[a] Averages and standard deviations were calculated from the results of analysis of 4 individual gasoline samples reported by Smallwood et al. (2002).
[b] For benzene only average and range are available, for toluene only two individual values were reported.
[c] (Rudolph et al., 2002).
[d] (Kawashima and Murakami, 2014).
[e] (Czapiewski et al., 2003).
[f] (Giebel et al., 2010).
[g] (Turner et al., 2006).

Table 9. Regression analysis of delta values. Values above diagonal are R^2, and below are the intercepts.

	Benzene[b]	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
Benzene[b]		<0.3	<0.3	<0.3	<0.3
Toluene	NA		0.361	0.356	0.335
Ethylbenzene	NA	-0.04 (4.31)[a]		0.820	0.963
o-Xylene	NA	-2.58 (4.31)	-2.54 (1.56)		0.825
p,m-Xylene	NA	-0.49 (4.57)	-0.19 (0.64)	-1.64 (1.63)	

[a] Standard error of intercept (‰) in parenthesis. The values are for linear fits of the mixing ratio of the more reactive VOC versus the mixing ratio of the less reactive VOC.
[b] No significant correlation was found for linear regressions of the mixing ratios of any of the VOC versus the mixing ratios of benzene.

1 **Table 10**. Summary of kinetic data, carbon isotope ratio of emissions, carbon isotope ratio
2 calculated for steady state between emission and loss, and average measured carbon isotope ratio
3 for light aromatic VOC[a].

Compound	k_{OH}[b] $(10^{-12}$ cm^3 molec^{-1} s^{-1})	ε_{OH} (‰)[c]	δ^{13}C source (‰)[d]	δ^{13}C steady state (‰)	Average of δ^{13}C measured (‰)
Benzene	1.22	7.83 (0.42)[e]	-28.0 (0.2)	-20.1 (0.5)	-25.0 (0.5)
Toluene	5.63	5.59 (0.28)	-27.6 (0.5)	-21.7 (0.5)	-24.8 (0.4)
Ethylbenzene	7.0	4.34 (0.28)	-27.7 (0.2)	-23.4 (0.4)	-24.0 (0.5)
o-Xylene	13.6	4.27 (0.05)	-27.2 (0.2)	-22.9 (0.2)	-23.3 (0.5)
p,m-Xylene	20.5[f]	4.83 (0.05)[g]	-27.4 (0.4)	-22.6 (0.4)	-24.0 (0.6)

4 [a]Values in parenthesis are the standard error of the mean.
5 [b] Rate constants for 298 K (Atkinson and Arey, 2003;Finlayson-Pitts and Pitts, 2000).
6 [c] Carbon kinetic isotope effects for reaction with OH radicals (Anderson et al., 2004a;Anderson
7 et al., 2004b;Rudolph et al., 2002).
8 [d] Isotopic composition of traffic related VOC emissions in Toronto (Rudolph et al., 2002).
9 [e] Average ε calculated from 8.13 (0.8) (Anderson et al., 2004b) and 7.53 (0.5) (Rudolph et al.,
10 2002).
11 [f] Average of $k_{OHp-xylene}=1.43 \times 10^{-11}$ cm^3 molec^{-1} s^{-1} and $k_{OHm-xylene}=2.36 \times 10^{-11}$ cm^3 molec^{-1} s^{-1}.
12 [g] ε_{OH} (‰) is for p-xylene, no value is available for m-xylene.
13

14 **Table 11.** Overview of the number of observations within different ranges of carbon isotope
15 ratios[a].

Range for δ^{13}C	Benzene	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
$<\delta^{13}C_{source}$[b]	1 (2%)	0	4 (7%)	4 (9%)	4 (7%)
$\approx\delta^{13}C_{source}$[c]	10 (23%)	32 (44%)	14 (24%)	5 (11%)	15 (27%)
$>\delta^{13}C_{source}$ **but**$<\delta^{13}C_{global}$[d]	28 (64%)	15 (21%)	4 (7%)	6 (14%)	4 (7%)
$\approx\delta^{13}C_{steady\ state}$[e]	2 (4 %)	23 (31%)	19 (33%)	17 (39%)	21 (38%)
$>\delta^{13}C_{steady\ state}$[f]	3 (7%)	3 (4 %)	17 (29%)	12 (27%)	12 (21%)
Total	44	73	58	44	56

16 [a] The value in parenthesis gives the percentage of observation. The confidence intervals used to
17 determine the δ^{13}C ranges were calculated from measurement error, uncertainty of δ^{13}C of
18 emissions, and uncertainty of ε_{OH}.
19 [b] Number of δ^{13}C measurements below the 95% confidence limit of δ^{13}C of emissions.
20 [c] Number of δ^{13}C measurements within the 95% confidence limit of δ^{13}C of emissions.
21 [d] Number of δ^{13}C measurements above the 95% confidence limit of δ^{13}C of emissions but below
22 the 95% confidence limit of δ^{13}C calculated for steady state between emissions and loss.
23 [e] Number of δ^{13}C measurements within the 95% confidence limits of δ^{13}C calculated for steady
24 state between emissions and loss.
25 [f] Number of δ^{13}C measurements above the 95% confidence limit of δ^{13}C calculated for steady
26 state between emissions and loss.
27

1 **Table 12.** Comparison of slopes calculated from Eq. 4 based on the assumption that different
2 VOC have identical $\int[OH]dt$ (above diagonal) with slopes determined from linear regression of
3 the observations (below diagonal).

	Benzene	Toluene	Ethylbenzene	o-Xylene	p,m-Xylene
Benzene		3.29	3.18	6.07	6.08
Toluene	NA[a]		0.97	3.15	1.85
Ethylbenzene	NA	0.96 (0.17)[b]		3.26	1.91
o-Xylene	NA	0.85 (0.18)[b]	0.89 (0.07)[b]		0.59
p,m-Xylene	NA	0.95 (0.18)[b]	1.0 (0.03)[b]	0.93 (0.07)[b]	

4 [a] Not available, no correlation found.
5 [b] Standard error in parenthesis.
6
7
8 **Table 13.** Overview of $\int[OH]dt$ [a] of light aromatic VOC calculated from their stable carbon
9 isotope ratios.

Compound	Mean[b]	Median[c]	90th percentile	75th percentile	25th percentile	10th percentile
Benzene	31 (5)	21(14)	76	49	11	-4.1
Toluene	8.5 (1.1)	5.7 (8)	21	12	1.6	0.61
Ethylbenzene	12.1 (1.7)	14 (5.7)	29	20	2.3	-2.8
o-Xylene	6.8 (0.9)	6.8 (2.6)	15	10	1.9	-1.5
p,m-Xylene	3.4 (0.6)	3.6 (2.4)	8.7	6.5	0.5	-1.0

10 [a] $\int[OH]dt$ in 10^{10} s molecules cm^{-3}.
11 [b] Standard error of mean in parenthesis.
12 [c] 95% confidence interval in parenthesis.

13

1 **Table 14.** Comparison of observed VOC concentration ratios (mol/mol) with VOC emission ratios for industrial facilities and mobile
2 transportation.

VOC concentration ratios	Facilities Ontario[a]	Facilities Toronto[a]	Gasoline engines[b]	Traffic Sarnia[c]	Traffic 8 European cities[d]	Average all observations
Toluene/Benzene	6.2	120	2.6±1.9	3.6	2.0±0.4	6.6±0.56
Ethylbenzene/Benzene	0.68	13	0.20±0.19	0.57	0.38±0.08	0.69±0.083
∑ Xylenes/Benzene	5.3	114	0.65±0.50	2.3	1.6±0.4	2.3±0.17
∑ Xylenes/Toluene	0.86	0.96	0.34±0.28	0.63	0.81±0.2	0.35±0.019
∑ Xylenes/Ethylenzene	7.9	8.6	4.0±1.3	4.1	4.1±0.5	3.5±0.096

3 [a] Calculated from emissions reported by the National Pollution Release Inventory (NPRI) for 2009 and 2010.
4 [b] Average and standard deviation calculated from 16 measurements of the composition of exhaust from of gasoline engines using
5 ethanol free or low ethanol fuel reported by the United States Environmental Protection Agency, Speciate Data Base.
6 [c] Calculated from average ratios reported by Miller et al. (2011) for ambient observations dominated by traffic related emissions in
7 Sarnia (Southern Ontario, Canada).
8 [d] Calculated from mixing ratios reported by Monod et al. (2001) for observations dominated by traffic related emissions in 8 major
9 cities in Europe.
10
11

1   **Table 15.** Comparison of observed VOC concentration ratios (mol/mol) for different dominant wind directions and different $\int[OH]dt$.

VOC concentration ratios	S+W[a]	N+E[b]	N+E Recent[c]	N+E Aged[c]
Toluene/Benzene	8.2±1.5	6.1±0.90	4.9±2.2	7.7±1.6
Ethylbenzene/Benzene	1.0±0.2	0.61±0.10	0.37±0.11	0.82±0.16
o-Xylene/Benzene	0.76±0.17	0.44±0.09	0.24±0.06	0.68±0.15
p,m-Xylene/Benzene	2.8±0.67	1.5±0.27	0.81±0.22	2.2±0.44
Ethylbenzene/Toluene	0.11±0.01	0.13±0.04	0.074±0.012	0.17±0.074

p,m-Xylene/o-Xylene	3.6±0.27	3.3±0.23	3.4±0.20	3.1±0.28
∑ Xylenes/Benzene	3.3±0.81	1.8±0.34	1.0±0.29	2.7±0.55
∑ Xylenes/Toluene	0.35±0.051	0.34±0.076	0.21±0.042	0.49±0.15
∑ Xylenes/Ethylenzene	3.3±0.17	3.5±0.34	2.8±0.21	4.1±1.1

2   [a] Average ratio for data with winds dominantly from southern or western sectors. Only data points for which at least during 80% of
3   the sampling time the wind direction was within ± 45° of the dominant wind direction are included. The number of data points is
4   between 14 and 20. The uncertainty stated is the standard error of the mean.
5   [b] Average ratio for data with winds dominantly from northern or eastern sectors are included. Only data points for which at least
6   during 80% of the sampling time the wind direction was within ± 45° of the dominant wind direction are included. The number of data
7   points is between 15 and 20. The uncertainty stated is the standard error of the mean.
8   [c] Data for the N+E sector filtered based on $\int[OH]dt$ determined from the p,m- xylene carbon isotope ratio. Aged refers to samples with
9    $\int[OH]dt > 0$ at the 99% confidence limit. The confidence limit was calculated from the uncertainty of the isotope ratio of emissions,
10   the measurement uncertainty and the uncertainty of the KIE. Recent represents samples with $\int[OH]dt$ below this limit. The values
11   given are the average ratios and the standard error of the mean. The number of data points for Recent is 5, for Aged there are between
12   7 and 9 values.

3 sampling by the National Air Pollution Surveillance Program (NAPS) in Toronto (A: Elmcrest
4 Road, Toronto, ON, Canada, B: 223 College St., Toronto, ON, Canada, C: 461 Kipling Ave.,
5 Toronto, ON, Canada. The map was produced using ©Google Earth, 2015.

6

7 **Figure 2.** Example plots for the dependence between mixing ratios for different VOC pairs.

8

9 **Figure 3**. Frequency distribution for VOC carbon isotope ratios measured in Toronto in 2009
10 and 2010. Observations for different seasons are identified as follows: Fall- dotted, winter- black,
11 and spring and summer- hatched. The solid vertical lines are the isotope composition of traffic
12 related emissions (Rudolph et al., 2002).

13

14 **Figure 4**. Example plots for the dependence between carbon isotope ratios for different VOC
15 pairs.

16

17 **Figure 5**.Example plots of VOC mixing ratios versus carbon isotope ratios.

18

19 **Figure 6**. Dependence between average $\int[OH]dt$ (photochemical age, PCA) and photochemical
20 life time for light aromatic VOC. The average tropospheric life time was calculated using the rate
21 constants given in Table 10 and an average tropospheric concentration of 1.16×10^6 OH-radicals
22 cm^{-3} (Spivakovsky et al., 2000). Vertical error bars are the standard error of the mean.

23

24 **Figure 7.** Dependence between the $\int[OH]dt$ (PCA) of different VOC and the $\int[OH]dt$ (PCA) of
25 p,m-xylene. Only data with $\int[OH]dt$ larger than zero at a 95 % confidence limit are shown.

26

27 **Figure 8.** Plot of VOC concentration ratios versus $\int[OH]dt$ (PCA) determined from carbon
28 isotope ratios. The lines show the change in carbon isotope ratios predicted for identical $\int[OH]dt$
29 of the different VOC.

30

31 **Figure 9.** Relative change of VOC concentration ratios and $\int[OH]dt$ (PCA) of benzene for
32 different ranges of $\int[OH]dt$ (in units of 10^{10} s molecules cm^{-3}) derived from the carbon isotope
33 ratio of p,m-xylene. The bars represent the ratio of the mean concentration ratios for the chosen
34 interval of $\int[OH]dt$ over the average for all concentration ratios. The error bars are the relative
35 standard errors of the mean. The range of $\int[OH]dt$ for the lowest $\int[OH]dt$ bin was chosen to
36 include all $\int[OH]dt$ which are not significantly larger than zero. (95 % confidence limit). The
37 other ranges were chosen to include between 8 and 12 data points in each bin.

38

39 **Figure 10.** Relative difference between the average of all VOC concentration ratios (mol/mol)
40 and the average VOC concentration ratios for VOC with carbon isotope ratios that are not higher
41 than the carbon isotope ratios of emissions (95 % confidence limit) (squares). The circles show
42 the relative change expected for a uniform $\int[OH]dt$ calculated from the average $\int[OH]dt$ of all

46

1 observations (Table 13). The error bars show the standard error calculated from error
2 propagation. For data points with error bars smaller that the size of the data point no error bars
3 are show.
4
5 **Figure 11.** Location of facilities in southern Ontario with significant emissions of xylenes. The
6 numbers represent the annual emissions in tons $year^{-1}$. Emission data were taken from the
7 National Pollutant Release Inventory (NPRI). Only sources contributing at least 5% to the total
8 emissions are shown. Also shown is the location of the sampling site. The map was produced
9 using ©Google Earth, 2015
10
