## 18 **Abstract**

19 Vertical profiles of dicarboxylic acids, related organic compounds and SOA tracer  
20 compounds in particle phase have not yet been simultaneously explored in East Asia, although  
21 there is growing evidence that aqueous phase oxidation of volatile organic compounds may be  
22 responsible for the elevated organic aerosols (OA) in the troposphere. Here, we found  
23 consistently good correlation of oxalic acid, the most abundant individual organic compounds  
24 in aerosols globally, with its precursors as well as biogenic-derived secondary OA (SOA)  
25 compounds in Chinese tropospheric aerosols by aircraft measurements. Anthropogenically  
26 derived dicarboxylic acids (i.e., C<sub>5</sub> and C<sub>6</sub> diacids) at high altitudes were 4-20 times higher than  
27 those from surface measurements and even occasionally dominant over oxalic acid at altitude  
28 higher than 2 km, which is in contrast to the predominance of oxalic acid previously reported  
29 globally including the tropospheric and surface aerosols. This indicates an enhancement of  
30 tropospheric SOA formation from anthropogenic precursors. Furthermore, oxalic acid-to-  
31 sulfate ratio maximized at altitude of ~2 km, explaining aqueous-phase SOA production that  
32 was supported by good correlations with predicted liquid water content, organic carbon and  
33 biogenic SOA tracers. These results demonstrate that elevated oxalic acid and related SOA  
34 compounds from both the anthropogenic and biogenic sources may substantially contribute to  
35 tropospheric OA burden over polluted regions of China, implying aerosol-associated climate  
36 effects and intercontinental transport.

## 37 **1 Introduction**

38 Water-soluble dicarboxylic acids (diacids), one of the most abundant organic aerosol  
39 (OA) constituents, have been reported in the marine (Kawamura and Sakaguchi, 1999), remote  
40 (Kawamura et al., 1996), desert (Sorooshian et al., 2012), mountainous, rural, semi-urban, and  
41 urban atmosphere (Ho et al., 2007). As important components of aerosols, diacids play an  
42 important role in Earth's climate by directly scattering sunlight or indirectly by enhancing the  
43 ability of OA to act as cloud condensation nuclei (CCN) (Kumar et al., 2003). They can

44 contribute to wide ranges from a few percent of the water-soluble mass (Sorooshian et al.,  
45 2007b), which could serve as tracers for the atmospheric processing of water-soluble OA  
46 (Ervens et al., 2011), to more than 10% of organic carbon (OC) in the remote marine  
47 atmosphere (Kawamura and Sakaguchi, 1999).

48         Diacids in aerosols may be directly emitted from fossil fuel combustion (e.g. vehicle  
49 exhaust) (Kawamura and Kaplan, 1987), biomass burning (Narukawa et al., 1999) and cooking  
50 emissions (Rogge et al., 1991). They can also be formed by degradation from unsaturated fatty  
51 acids (Kawamura et al., 1996) and cyclic alkenes (Hatakeyama et al., 1987). Laboratory studies  
52 have provided direct experimental evidence that stepwise aqueous oxidation of relatively  
53 longer-chain (n) dicarboxylic acids can yield the corresponding short-chain (n-1) dicarboxylic  
54 acids (Enami et al., 2015). In addition, in-cloud and below-cloud measurements as well as other  
55 field measurements have revealed that aqueous-phase oxidation of volatile organic compounds  
56 (VOCs) and intermediates such as glyoxal (Gly), methylglyoxal (MeGly) and pyruvic acid (Pyr)  
57 in wet aerosols or clouds and the subsequent gas-particle partitioning are more important  
58 pathway for the production of small diacids such as oxalic and malonic acids (Lim et al.,  
59 2013;Carlton et al., 2007;Lim et al., 2005;Carlton et al., 2006;Yu et al., 2005;Sorooshian et al.,  
60 2007b;Sorooshian et al., 2006;Zhang et al., 2016). Oxalic acid (C<sub>2</sub>) is the most abundant diacid  
61 with concentrations ranging from a few ng m<sup>-3</sup> in remote locations (Kawamura et al., 1996) to  
62 hundreds or even up to one thousand ng m<sup>-3</sup> in urban regions (Ho et al., 2007) and highly  
63 forested regions (Falkovich et al., 2005). Indeed, from a model study it has been proposed that  
64 photochemical oxidation of isoprene and subsequent partitioning of water soluble  
65 photooxidation products into the aqueous phase is a predominant formation pathway of oxalic  
66 acid (Myriokefalitakis et al., 2011). Most of the previous studies of diacids and other organic  
67 compounds in aerosols have been conducted at ground surface; however, only a few aircraft  
68 observations that have been conducted over the arctic region (Talbot et al., 1992), the western  
69 North Pacific (Narukawa et al., 1999), the western rim of the Pacific Ocean (Kawamura et al.,  
70 2003), the coastal marine stratocumulus and cumulus clouds over USA (Crahan et al.,

71 2004;Sorooshian et al., 2013;Sorooshian et al., 2007a;Wonaschuetz et al., 2012;Prabhakar et  
72 al., 2014) and over inland agricultural and urban areas in the western United States (Sorooshian  
73 et al., 2015). These aircraft experiments have revealed that water-soluble diacids may be  
74 produced by the photochemical oxidation of anthropogenic organic compounds in the  
75 atmosphere and thus play an important role in controlling the chemical and physical properties  
76 of OA in the troposphere. However, the evidence of secondary production of diacids (i.e., oxalic  
77 acid) in tropospheric aerosols may be not enough due to the lack of dataset from simultaneous  
78 measurements of their possible precursors and/or intermediates such as particle-phase glyoxal  
79 (Gly), methylglyoxal (MeGly), pyruvic acid (Pyr) and glyoxylic acid ( $\omega$ C<sub>2</sub>) as well as other  
80 secondary organic aerosol (SOA) compounds from photochemical oxidation of VOCs such as  
81 isoprene and monoterpenes in the aerosols collected from aircraft campaigns.

82 East Asia is one of the most important source regions of OA (Zhang et al., 2007), and  
83 this is especially true for China due to the rapid urbanization, industrialization and energy  
84 consumption (Huang et al., 2014;Zhang et al., 2015a;Zhang and Cao, 2015). Elevated OA were  
85 found in the free troposphere from ACE-Asia aircraft observations, exceeding model-predicted  
86 organic aerosols by a factor of 10-100 (Heald et al., 2011;Heald et al., 2005;Henze and Seinfeld,  
87 2006). There is growing evidence that SOA formation from aqueous phase processing of VOCs,  
88 especially from isoprene may partially explain the missing OA in the troposphere over East  
89 Asia (Heald et al., 2011;Heald et al., 2005;Henze and Seinfeld, 2006), however, vertical  
90 profiles of diacids, related organic compounds (i.e., ketoacids and  $\alpha$ -dicarbonyls) and SOA  
91 tracer compounds in particle phase have not yet been simultaneously analyzed in this region.  
92 Additional chemical constraints (e.g. simultaneously measuring different types of organic  
93 aerosols such as diacids, ketoacids and  $\alpha$ -dicarbonyls and SOA tracer compounds) are urgently  
94 required to investigate the importance of SOA formation pathway to the global/regional budget  
95 of OA. Our previous studies have reported the molecular composition of primary organic  
96 aerosols (POA) including n-alkanes, fatty acids, sugars, and polycyclic aromatic hydrocarbons  
97 (PAHs) as well as biogenic SOA tracers in aerosol particles over China (Wang et al., 2007;Fu

98 et al., 2014). However, chemical composition and molecular distribution of diacids have never  
99 been reported by aircraft measurements over mainland and coastal China, although only limited  
100 studies have been conducted on their spatial distributions based ground observations (Ho et al.,  
101 2007).

102 In this study, we have collected aerosol samples over coastal to inland China using  
103 aircraft during spring, summer and winter. The samples were analyzed for a series of diacids  
104 and related compounds as well as SOA tracer compounds to investigate the vertical profiles,  
105 possible sources and formation pathways of diacids and related organic compounds in the  
106 polluted troposphere over China. In light of these analyses, we observed that production of  
107 oxalic acid and related compounds from anthropogenic and biogenic precursors is enhanced at  
108 high altitudes in the troposphere.

## 109 **2 Materials and Methods**

### 110 **2.1 Aircraft Campaigns**

111 Aircraft measurements were carried out over the coastal East China Sea in winter  
112 (12/25/2002–01/06/2003, n=18) and inland China during summer (08/08/2003–09/13/2003,  
113 n=14) and spring (05/19/2004–06/10/2004, n=16) using Yun-12 and Yun-5 airplanes as  
114 described elsewhere(Wang et al., 2007;Fu et al., 2014) . The sampling heights were from 500  
115 m to 3000 m (with uncertainty of around 10%) above ground level across many major cities  
116 such as Changzhou, Nanjing, Hefei, Wuhan, Chongqing and Chengdu for inland aerosol  
117 samples as well as Wenzhou, Ningbo, Shanghai, Changzhou, Qingdao and Dalian for coastal  
118 aerosol samples. The detailed flight tracks and flight information are shown in Figure 1 and  
119 Table S1 (see Supporting Information). PM<sub>2.5</sub> aerosols were collected on pre-heated quartz  
120 fiber filter (diameter of 90 mm) using a medium-volume air sampler (Beijing Geological  
121 Instrument Factory, China). Aerosol samples were collected for the sampling period from ca.  
122 80 min. to two hours. Air was taken via an inlet installed below the cabin of the aircraft at a  
123 flow rate of 78 L/min. The lack of using organic denuders may lead to a positive artifact (e.g.,

124 10% of the organic carbon) by possible adsorption of gas-phase organic acids on the quartz  
125 filters (Cheng et al., 2009), but this will not affect our conclusions. Because air conditioning  
126 was not available in the aircraft, the ambient temperatures inside and outside the cabin should  
127 be similar, and thus potential adsorption of gaseous organic acids on quartz filter should be  
128 minimal.

## 129 **2.2 Measurement of diacids**

130 Diacids and related organic compounds such as  $\omega$ -oxocarboxylic acids (or oxoacids),  
131 pyruvic acid and  $\alpha$ -dicarbonyls were determined as described elsewhere (Kawamura and  
132 Ikushima, 1993;Ho et al., 2010). Briefly, the sample and blank filters were extracted with  
133 organic free ultrapure water (10 ml  $\times$  3) in a glass vial for 10 min. To remove insoluble particles  
134 and filter debris, the extracts were passed through a Pasteur pipette packed with quartz wool.  
135 The combined extracts were concentrated using a rotary evaporator under a vacuum and then  
136 further concentrated using a nitrogen blow-down system. The concentrated extracts were  
137 reacted with 14%  $\text{BF}_3$ /n-butanol to derive carboxyl group to dibutyl ester and oxo group to  
138 dibutoxy acetals.

139 The derivatives were extracted with n-hexane, concentrated to near dryness, dissolved  
140 with n-hexane in 1.5 ml glass vials. The samples were finally determined using a gas  
141 chromatography (GC, HP6980) with a split/splitless injection, fused silica capillary column  
142 (HP-5, 0.2 mm i.d.  $\times$  25 m long  $\times$  0.52  $\mu\text{m}$  film thickness) and a flame ionization detector.  
143 Identification of the compounds was performed by GC retention times with those of authentic  
144 standards and GC/mass spectrometry analyses. Recoveries of authentic standards spiked to a  
145 pre-heated quartz fiber filter were generally better than 85% for all organic compound identified  
146 except for oxalic acid (78%), pyruvic acid (72%), and methylglyoxal (55%). Duplicate analyses  
147 of filter samples from other sites indicated that analytical errors are smaller than 15%. During  
148 the aircraft campaigns, field blank filters were mounted onto the sampler for seconds without  
149 pumping. Blank and sample filters were placed individually in a clean (pre-combusted at 450

150 °C for 6 h) glass jar sealed with a Teflon-lined screw cap, transported to the laboratory, and  
151 stored at -20 °C prior to analysis (Wang et al., 2007).

152 Small peaks of oxalic, malonic and glyoxylic acids were found in the field and lab  
153 blanks, but they were smaller than 10% of the real samples. The concentrations reported here  
154 are all corrected for the field blanks but not for the recoveries. The method of SOA tracers  
155 measurement was described elsewhere (Fu et al., 2014) .

### 156 **2.3 Measurements of EC and OC**

157 The concentrations of organic carbon (OC) and elemental carbon (EC) were measured  
158 with thermal-optical transmittance method by OC/EC Carbon Aerosol Analyzer (Sunset  
159 Laboratory Inc., USA) following the IMPROVE protocol (Chow et al., 2004). All the analyses  
160 of the filter samples were completed in 2006.

### 161 **2.4 Estimation of liquid water content and aerosol acidity**

162 Liquid water content (LWC) and aerosol acidity were predicted by ISORROPIA II,  
163 which is a thermodynamic equilibrium model with robust and rapid convergence for all aerosol  
164 types (Fountoukis and Nenes, 2007). Measured concentrations of water-soluble inorganic ions,  
165 ambient temperature and relative humidity were used as input.

## 166 **3 Results and discussion**

### 167 **3.1 Concentrations and molecular distributions**

168 Total concentrations of diacids and related compounds quantified in the inland aircraft  
169 PM<sub>2.5</sub> (i.e., particulate matter with a diameter smaller than 2.5 μm) are 730±328 and 586±457  
170 ng m<sup>-3</sup> during summer and spring, respectively, while in the coastal aerosols, the average  
171 concentration is 254±209 ng m<sup>-3</sup> in winter (Table 1). It is of great interest to note that the  
172 concentrations of diacids in the troposphere over the Arctic and North Pacific are generally  
173 much lower than those reported at ground levels (Kawamura et al., 1996;Kawamura and

174 Sakaguchi, 1999); however, the concentrations in the troposphere over mainland China are  
175 within the range of or even higher than those reported at ground levels in major cities (Ho et  
176 al., 2007; Kawamura and Ikushima, 1993). Due to the enhanced anthropogenic emissions,  
177 concentrations of POA (i.e., n-alkanes, fatty acids, sugars, lignin and resin products, sterols,  
178 PAHs, and phthalic acids) are higher in winter than those in summer and spring (Wang et al.,  
179 2007). In contrast, the concentrations of diacids in summer and spring are 2-15 times higher  
180 than those in winter, indicating that these compounds are mostly of secondary origin via the  
181 oxidation of their gaseous precursors such as isoprene and  $\alpha/\beta$ -pinene (Kanakidou et al.,  
182 2005; Carlton et al., 2006; Carlton et al., 2007; Carlton et al., 2009; Ervens et al., 2011) as  
183 discussed below.

184 Molecular distributions of diacids ( $C_n$  is n-numbered carbon diacid) in our study are  
185 generally characterized by the predominance of oxalic acid ( $C_2$ ) followed by succinic ( $C_4$ ) and  
186 malonic ( $C_3$ ) acids during spring and winter, being consistent with previous findings obtained  
187 in Chinese megacities (Ho et al., 2007) (Figure 2a). However, in many summer samples  
188 collected at height of above 2 km, we found the predominance of glutaric ( $C_5$ ) and adipic ( $C_6$ )  
189 acids (see Figure 2b), which are the major organic compounds produced by the oxidation of  
190 anthropogenic cyclohexene and methylenecyclohexane (Hamilton et al., 2006; Muller et al.,  
191 2007). Although  $C_5$  and  $C_6$  diacids are the ozonolysis products in smog chamber studies,  
192 Pavuluri et al. (2015) recently proposed that  $C_5$  and  $C_6$  are produced by photochemical  
193 processing of aqueous aerosols from a laboratory study. Such a molecular distribution has not  
194 been reported for the tropospheric and ground level aerosols (Hatakeyama et al., 1987; Enami  
195 et al., 2015; Kawamura and Bikkina, 2016). In our measurements, the averaged concentrations  
196 of  $C_5$  and  $C_6$  in summer are  $159 \pm 79 \text{ ng m}^{-3}$  and  $93.9 \pm 23.2 \text{ ng m}^{-3}$ , which are 4-20 times higher  
197 than those in ground measurements in many megacities in China (Ho et al., 2007), Tokyo  
198 (Kawamura and Yasui, 2005) and Los Angeles (Kawamura and Kaplan, 1987). Such high  
199 abundances of  $C_5$  and  $C_6$  observed in summer imply an important formation pathway associated

200 with enhanced photochemical oxidation of anthropogenic precursors in the polluted  
201 troposphere over China.

### 202 **3.2 C<sub>3</sub> (C<sub>2</sub>) to C<sub>4</sub> ratio**

203 The malonic to succinic acid (C<sub>3</sub>/C<sub>4</sub>) ratios can provide information on source,  
204 formation pathways and photochemical aging of organic aerosols. C<sub>3</sub>/C<sub>4</sub> ratios in aerosols  
205 derived from vehicular exhausts (i.e., 0.25–0.44, av. 0.35) (Kawamura and Kaplan, 1987) have  
206 lower values than those in ambient aerosols from Tokyo (i.e., 0.56–2.9, av. 1.6) (Kawamura  
207 and Ikushima, 1993) and China's megacities (i.e., 0.6–1.1, average 0.74) (Ho et al., 2007). In  
208 contrast, the ratios are substantially higher for aged aerosols because C<sub>3</sub> is more produced by  
209 photochemical processing of C<sub>4</sub> (Kawamura and Ikushima, 1993). Actually, higher C<sub>3</sub>/C<sub>4</sub> ratios  
210 are observed for remote marine aerosols from the North Pacific including tropic (range: 1–11,  
211 av. 3.9) which are subjected to extensive aging during the long-range atmospheric transport  
212 (Kawamura and Sakaguchi, 1999). In this study, C<sub>3</sub>/C<sub>4</sub> ratios are 0.5±0.4 in summer, 0.9±0.1  
213 in spring (Table 1), and 0.7±0.2 in winter, apparently smaller than those in aerosols affected by  
214 atmospheric aging, but similar to that of urban aerosols in China (i.e., 0.9 in summer and 0.6 in  
215 winter) (Ho et al., 2007). In addition, C<sub>3</sub> and C<sub>4</sub> can be formed by OH reactions of water soluble  
216 organic compounds such as glyoxal (Tan et al., 2009) and C<sub>3</sub>/C<sub>4</sub> ratios gradually decrease with  
217 the reaction time (Pavuluri et al., 2015). The lower C<sub>3</sub>/C<sub>4</sub> ratios in summer indicate that diacid  
218 aerosols are relatively fresh but will be subjected to more atmospheric aging than in other  
219 seasons due to increasing OH concentrations and solar radiation.

220 C<sub>2</sub>/C<sub>4</sub> ratios (2.0 in summer, 4.6 in spring and 4.6 in winter) in our study are found to  
221 be much smaller than those from ground observations in China during summer (inland cities in  
222 summer: av. 7.1) and winter (coastal cities in winter: av. 7.9). The lower C<sub>2</sub>/C<sub>4</sub> and C<sub>3</sub>/C<sub>4</sub> ratios  
223 could be also resulting from degradation of C<sub>2</sub> and C<sub>3</sub> in high altitudes due to increased solar  
224 radiation. However, no strong correlation ( $p>0.05$ ) is found between C<sub>2</sub>/C<sub>4</sub> (and C<sub>3</sub>/C<sub>4</sub>) and  
225 sampling altitude although solar radiation is expected to increase with increasing altitudes.

226 These results suggest that the degradation of higher homologous diacids (i.e., C<sub>4</sub>) is not an  
227 important pathway for the production of tropospheric C<sub>2</sub> and C<sub>3</sub> in China, and primary fossil-  
228 fuel emissions and/or secondary production from other precursors are major formation  
229 pathways of these small diacids (i.e., C<sub>2</sub>, C<sub>3</sub> and C<sub>4</sub>).

### 230 3.3 Cis/trans ratio

231 It has been revealed that maleic acid (M, *cis* configuration) is produced by  
232 photochemical oxidation of anthropogenic aromatic hydrocarbons such as benzene and toluene,  
233 which is predominant over fumaric acid (F, *trans* configuration) (Sempere and Kawamura,  
234 1996). M can be photo-isomerized to its *trans* isomer (F) in the atmosphere under solar  
235 radiation. M/F ratios (4.9, 4.5 and 6.8 for summer, spring and winter, respectively) are much  
236 higher in the present study than those reported in marine region (0.1-1.5) (Fu et al., 2013) and  
237 Chinese megacities at ground levels (2.0 and 2.2 for summer and winter, respectively) (Ho et  
238 al., 2007). This indicates that only a small fraction of maleic acid is isomerized to fumaric acid  
239 by photochemical transformation and thus SOA produced from anthropogenic emissions in the  
240 lower/middle troposphere in China is mostly fresh without substantially photochemical  
241 processing (Cong et al., 2015).

### 242 3.4 C<sub>5</sub> (C<sub>6</sub>) to C<sub>9</sub> diacid ratio

243 C<sub>6</sub> (or C<sub>5</sub>) to azelaic acid (C<sub>9</sub>) ratio (i.e., C<sub>6</sub>/C<sub>9</sub> or C<sub>5</sub>/C<sub>9</sub>) is often used as an indicator  
244 of relative contribution from anthropogenic and biogenic sources to OA (Kawamura and Yasui,  
245 2005). C<sub>6</sub>/C<sub>9</sub> and C<sub>5</sub>/C<sub>9</sub> ratios during the summer aircraft campaign are on average 17 and 28,  
246 respectively, which are >15 times higher than those reported at the ground surface from major  
247 Chinese cities (Ho et al., 2007; Wang et al., 2002). This comparison further supports that  
248 anthropogenic sources are an important source of OA in the high altitudes over China. Taken  
249 together with other possible SOA components (e.g., oligomers with MW > 250 Da) produced  
250 during the oxidation of anthropogenic VOCs, our result implies that SOA formation plays an  
251 important role in OA budget in the troposphere especially during summer when atmospheric

252 oxidation capacity is significantly enhanced (Shen and Wang, 2012; Su et al., 2012). It is  
253 important to note that the correlation coefficient of C<sub>6</sub> (or C<sub>5</sub>) with C<sub>2</sub> during summer ( $r^2=0.39$   
254 or 0.49) is lower than that obtained in winter ( $r^2=0.76$  or 0.59) and spring ( $r^2=0.95$  or 0.96),  
255 suggesting that C<sub>2</sub> has a different formation pathway and/or its precursors are mostly from  
256 biogenic origins (i.e., isoprene) in summer.

### 257 **3.5 Correlation of diacids with SOA tracers and biomass burning tracers**

258 In the urban atmosphere, dicarboxylic acids can be emitted as primary particles from  
259 motor exhausts (Kawamura and Kaplan, 1987), biomass burning (Cong et al., 2015; Falkovich  
260 et al., 2005), and cooking emissions (Rogge et al., 1991). However, recent field, laboratory and  
261 model studies have demonstrated that aqueous-phase SOA formation from isoprene or other  
262 precursors photooxidation is a major formation pathway of small diacids (Myriokefalitakis et  
263 al., 2011; Carlton et al., 2006; Ervens et al., 2011). Furthermore, significant correlations ( $r>0.70$ ,  
264  $p<0.05$ ) are obtained between C<sub>2</sub> and its possible precursors and intermediates such as glyoxylic  
265 acid ( $\omega$ C<sub>2</sub>), pyruvic acid (Pyr), glyoxal (Gly) and methylglyoxal (MeGly) in all three campaigns  
266 (Table 2). This demonstrates that C<sub>2</sub> is produced from its precursor compounds such as Pyr,  
267 Gly and MeGly through the following formation pathways: (CH<sub>3</sub>COCOOH, HCO-CHO,  
268 CH<sub>3</sub>COCHO) → HCO-COOH → HOOC-COOH (Carlton et al., 2009; Carlton et al.,  
269 2007; Carlton et al., 2006; Lim et al., 2013). We found that the correlation coefficient between  
270 Gly and C<sub>2</sub> is higher than that between MeGly and C<sub>2</sub> for winter and spring samples, being  
271 consistent with the fact that oxalic acid is the dominant product of glyoxal with the high yield  
272 but not for methylglyoxal (Tan et al., 2009; Lim et al., 2010). Indeed, a good correlation (Figure  
273 3) was found between predicted liquid water content with both OC and oxalic acid, indicating  
274 an important contribution from SOA formation via cloud processing and/or aqueous-phase  
275 oxidation. Aqueous-phase production of oxalic acid and related compounds may increase the  
276 abundances of SOA at the middle troposphere (around 2 km in this study), as discussed below.  
277 With the GEOS-Chem model based on the Fu et al. (2008) scheme (Fu et al., 2008), aqueous-  
278 phase SOA has a pronounced enhancement in the lower free troposphere (2-6 km) (Heald et al.,

279 2011), which may explain to some extent the elevated levels of oxalic acid around at ~2 km in  
280 altitude.

281 Similarly, C<sub>2</sub> also shows better correlations with both anthropogenic-derived SOA such  
282 as C<sub>5</sub> and C<sub>6</sub> for winter ( $r^2=0.76$  or  $0.59$ ) and spring ( $r^2=0.95$  or  $0.96$ ) samples than summer  
283 samples ( $r^2=0.39$  or  $0.49$ ), further supporting that anthropogenic VOCs play a more important  
284 role in SOA formation than biogenic VOCs during winter and spring. A recent study reveals  
285 that air pollutants such as SO<sub>2</sub>, NO<sub>2</sub>, PM<sub>2.5</sub> and PM<sub>10</sub> are higher in winter than in summer and  
286 spring and these air pollutants are mostly from anthropogenic emissions (Zhang and Cao, 2015).  
287 No significant correlation ( $r^2=0.28$ ,  $p>0.05$ ) is found between EC (i.e., a primary tracer for  
288 fossil fuel biomass combustion (Zhang et al., 2015b)) and C<sub>2</sub> in summer aerosols, whereas a  
289 good correlation is found in spring. These results indicate that primary emissions are not major  
290 sources of C<sub>2</sub> during summer, but their contribution may be more important in spring.

291 Oxalic acid shows a strong positive correlation with isoprene-derived SOA tracers such  
292 as 2-methylglyceric acid (2-MGA) and C<sub>5</sub>-alkene triols (cis-2-methyl-1,3,4-trihydroxy-1-  
293 butene,3-methyl-2,3,4-trihydroxy-1-butene plus trans-2-methyl-1,3,4-trihydroxy-1-butene)  
294 (Figure 4), but a very weak correlation ( $r^2 = 0.26$ ,  $p>0.05$ ) with 2-methyltetrols (2-  
295 methylthreitol and 2-methylerythritol). Previous studies have revealed that 2-methyltetrols  
296 could be formed through epoxy derivatives of isoprene through acid-catalyzed hydrolysis  
297 (Wang et al., 2005), whereas 2-MGA is produced by further gas-phase oxidation of its  
298 intermediates such as methacrolein and methacrylic acid from isoprene (Claeys et al.,  
299 2004;Surratt et al., 2006). Such a good correlation between 2-MGA and oxalic acid could  
300 demonstrate that oxalic acid has a very close link with the higher-generation products of  
301 isoprene in the presence of relatively high NO<sub>x</sub> (i.e., NO<sub>x</sub> averaged to  $6.6\pm 4.0$  ppbv in summer  
302 and  $3.9\pm 3.3$  ppbv), which could serve as precursors of oxalic acid over China. Oxalic acid also  
303 significantly correlates with  $\alpha/\beta$ -pinene-SOA tracers (i.e., pinonic, pinic, 3-hydroxyglutaric,  
304 and 3-methyl-1,2,3-butanetricarboxylic acid) and  $\beta$ -caryophyllene tracer ( $\beta$ -caryophyllinic acid,  
305 see Figure 4) (Jaoui et al., 2013).

306 Overall, both oxalic acid and SOA tracers are more abundant in summer than in spring,  
307 suggesting that production of these organics is associated with higher oxidation capacity,  
308 emission strength and solar radiation in summer. Based on the consistent good correlations of  
309 oxalic acid with SOA tracers derived from isoprene, monoterpene and  $\beta$ -caryophyllene, we  
310 propose that a large fraction of oxalic acid in the lower/middle troposphere over China is of  
311 secondary origin, i.e., via aqueous chemistry. This study highlights that oxalic acid may serve  
312 as an important tracer of SOA formation not only on the ground surface but also at high altitudes  
313 within the lower/middle troposphere. Therefore, the high abundances of small diacids ( $C_2$ - $C_6$ )  
314 observed in this study imply an important contribution to the OA budget from SOA production  
315 from both biogenic and anthropogenic precursors emitted from the ground surface to high  
316 altitudes over inland China.

317 The observed total concentrations of oxalic acid and other diacids identified in this  
318 study (Table 1) show the same magnitude as the levels of SOA (i.e.,  $299\pm 173$  ng m<sup>-3</sup> in summer  
319 and  $257\pm 210$  ng m<sup>-3</sup> in spring) estimated by SOA-tracer methods (Fu et al., 2014). It should be  
320 noted that oxalic acid is not included in the traditional “SOA tracer method” (Kleindienst et al.,  
321 2007) and therefore SOA may be underestimated if SOA is calculated by this approach.  
322 Although oxalic acid has relatively high vapor pressure, it has been observed as the most  
323 abundant individual organic compounds in aerosols (Kawamura and Bikkina, 2016). Our study  
324 together with many previous studies have revealed that oxalic acid is mostly from aqueous-  
325 phase production and is therefore of secondary origin (Myriokefalitakis et al., 2011). In addition,  
326 oxalic acid may partly exist as hydrated and/or salt forms in aerosols. Therefore, it is important  
327 to consider oxalic acid or oxalate as important SOA tracers.

328 Levoglucosan (1,6-Anhydro- $\beta$ -D-glucopyranose) has been used as a source tracer for  
329 biomass burning (Liu et al., 2013;Fu et al., 2012). Levoglucosan shows a significant correlation  
330 with oxalic acid and also secondary organic aerosol (SOA) tracers (Figure 5), indicating that  
331 biomass burning is an important source of oxalic acid and SOA. It is interesting to note that  
332 levoglucosan was more abundant in spring than in summer. In addition, regression slope and

333 correlation coefficient between oxalic acid and levoglucosan are higher in spring (i.e., slope:  
334 2.7, r: 0.95) than in summer (i.e., slope: 1.7, r: 0.67), indicating that biomass-burning emissions  
335 play more important roles in spring than summer. Such higher values of slope of regression line  
336 and correlation coefficient were also found between levoglucosan and  $\alpha/\beta$ -pinene- and  $\beta$ -  
337 caryophyllene-oxidation products, emphasizing an importance of springtime biomass burning.  
338 However, isoprene-oxidation products have a higher correlation coefficient in summer than in  
339 spring, implying that biomass burning in summer is an important contributor of isoprene-  
340 derived SOA.

### 341 **3.6 Vertical profiles of diacids**

342 As shown in Figure 6, the highest concentrations of oxalic acid and total diacids are  
343 observed around at 2 km in altitude during summer with a sharp decrease toward 3 km.  
344 However, during spring and winter, their concentrations decrease with increasing altitudes due  
345 to the atmospheric dilution during upward transport. Much clear trends are observed in the  
346 vertical profiles of oxalic acid normalized by anthropogenic tracers such as sulfate ( $\text{SO}_4^{2-}$ ),  
347 vanadium, and bulk OC. Interestingly, similar trends are also found in spring and winter  
348 samples, but the trends are weaker, suggesting that a secondary production of oxalic acid is  
349 largely enhanced during summer in the upper troposphere (~2 km). Similar vertical pattern has  
350 been also reported for biogenic SOA-tracers such as 2-MGA, 3-HGA and MBTCA (3-methyl-  
351 1,2,3-butanetricarboxylic acid), but not for POA such as biomass burning tracers (e.g.,  
352 levoglucosan), fungal spore tracers (arabitol and mannitol), sucrose, and trehalose (Fu et al.,  
353 2014). These results further demonstrate that oxalic acid is mostly likely produced by secondary  
354 process in the troposphere.

355 Oxalic acid in the high altitudes could not be simply explained by uplifting transport  
356 of pre-existing SOA produced on the ground surface because these SOA compounds relative  
357 to anthropogenic tracers such as  $\text{SO}_4^{2-}$ , vanadium, and OC significantly increased with altitude  
358 as stated above. This finding suggests that in-situ SOA production by the oxidation of VOCs

359 lifted from ground surface substantially contributes to the observed levels of oxalic acid and  
360 related species. Therefore, SOA formation in cloud or wet aerosol via the oxidation of biogenic  
361 and anthropogenic VOCs may increase concentrations of oxalic acid at higher altitudes in the  
362 troposphere. There is growing evidence to support of in-cloud formation of oxalic acid and  
363 related SOA. Many studies suggest that oxalic acid is mostly produced via aqueous-phase  
364 oxidation of water-soluble organics such as glyoxal, methylglyoxal, pyruvic acid and glyoxylic  
365 acid, which are oxidation intermediates of various VOCs (Ervens et al., 2004;Carlton et al.,  
366 2006;Ervens et al., 2011).

#### 367 **4 Conclusions**

368 Based on three aircraft measurements over East Asia, this study demonstrates an  
369 aqueous-phase mechanism for SOA productions of diacids in the troposphere following  
370 correlation analysis of oxalic acid in tropospheric aerosols with other measured chemical  
371 variables including its precursors and its intermediate as well as biogenic-derived SOA from  
372 isoprene, monoterpenes and  $\beta$ -caryophyllene. In addition to biogenic-derived SOA compounds,  
373 anthropogenic-derived dicarboxylic acids (e.g. C5 and C6 diacids) are 4-20 times higher than  
374 those from ground measurements and even occasionally dominant over oxalic acid at altitudes  
375 higher than 2 km in summer, which is in contrast to the predominance of oxalic acid previously  
376 reported globally including the tropospheric and surface aerosols. The results suggest an  
377 important formation pathway associated with enhanced photochemical oxidation of  
378 anthropogenic precursors in the polluted troposphere over China. Their relative contribution of  
379 anthropogenic and biogenic sources is subject to future studies. The combination of radiocarbon  
380 ( $^{14}\text{C}$ ) measurement of water-soluble organic carbon (WSOC) and specific SOA compounds  
381 (e.g., oxalic acid) may provide better insights on biogenic and fossil sources of SOA (Zhang et  
382 al., 2014;Zhang et al., 2015a;Noziere et al., 2015) .

383 The present study demonstrates that secondary formation of oxalic acid in aqueous  
384 phase plays an important role in the SOA budget from the near surface to the lower FT (i.e., 2

385 km) over inland China, whereas dilution of pre-existing particles and VOCs, photochemical  
386 decomposition and aerosol processing may decrease the levels of oxalic acid and related  
387 compounds at higher altitudes (>2 km). Our findings also highlight that water-soluble diacids  
388 and other SOA components may have important impacts on the chemical compositions,  
389 physical properties and budget of OA in the polluted troposphere over China, and thus  
390 significantly affect the regional/global climate and intercontinental transport especially over  
391 the Pacific Ocean.

## 392 **Acknowledgements**

393 The data reported in the paper are presented in the Supplementary Materials or are  
394 available upon request from the Y.-L.Z. The authors acknowledge the Ministry of Education,  
395 Culture, Sports, Science and Technology for financial support to perform the aircraft campaigns  
396 through Scientific Research on Priority Areas on Atmospheric Environmental Impacts of  
397 Aerosols in East Asia (no. 416, 2002–2005). The authors also acknowledge Dr. Hong Li from  
398 Chinese Research Academy of Environmental Sciences for her support and help during the  
399 aircraft measurements. This study was also supported by a grant-in-aid no. 14204055 and  
400 24221001 from the Japan Society for the Promotion of Science (JSPS).
