7
8 **Abstract.** In an attempt to improve the forecasting of atmospheric aerosols, the
9 ensemble square root filter algorithm was extended to simultaneously optimize the
10 chemical initial conditions and emission input. The forecast model, which was
11 expanded by combining the Weather Research and Forecasting with Chemistry
12 (WRF-Chem) model and a forecast model of emission scaling factors, generated both
13 chemical concentration fields and emission scaling factors. The forecast model of
14 emission scaling factors was developed by using the ensemble concentration ratios of
15 the WRF-Chem forecast chemical concentrations and also the time smoothing
16 operator. Hourly surface fine particulate matter (PM_{2.5}) observations were assimilated
17 in this system over China from 5 to 16 October 2014. A series of 48-h forecasts were
18 then carried out with the optimized initial conditions and emissions on each day at
19 0000 UTC and a control experiment was performed without data assimilation. Besides,
20 we also performed an experiment of pure assimilation chemical ICs and the
21 corresponding 48-h forecasts experiment for comparison. The results showed that the
22 forecasts with the optimized initial conditions and emissions typically outperformed
23 those from the control experiment. In the Yangtze River delta (YRD) and the Pearl
24 River delta (PRD) regions, large reduction of the Root Mean Square Errors (RMSEs)
25 was obtained for almost the entire 48-h forecast range attributed to assimilation.
26 Especially, the relative reduction in RMSE due to assimilation was about 37.5% at
27 nighttime when WRF-Chem performed comparatively worse. In the Beijing–Tianjin–
28 Hebei (JJJ) region, relatively smaller improvements were achieved in the first 24-h
29 forecast but then no improvements were achieved afterwards. Comparing to the
30 forecasts with only the optimized ICs, the forecasts with the joint adjustment were

31 always much better during the night in the PRD and YRD regions. However, they
32 were very similar during daytime in both regions. Also, they performed similarly for
33 almost the entire 48-h forecast range in the JJJ region.

34

35 **1. Introduction**

36 Aerosol prediction by regional air quality model in heavy polluted regions is
37 challenging due to many factors. In addition to the deficiency of chemistries, the
38 uncertainties of primary and precursor emissions and the initial conditions (ICs) also
39 limit the forecast accuracy. Data assimilation (DA), which is used to improve the ICs
40 of aerosols and to optimize data on aerosol emissions, has been shown to be one of
41 the most effective ways to improve the forecasting of aerosol pollution.

42 From the perspective of reducing the uncertainties in the ICs for aerosols, recent
43 efforts have focused on assimilating aerosol observations using optimal interpolation
44 (Collins et al., 2001; Yu et al., 2003; Adhikary et al., 2008; Tombette et al., 2009; Lee
45 et al., 2013) or variational (Kahnert, 2008; Zhang et al., 2008; Benedetti et al., 2009;
46 Pagowski et al., 2010; Liu et al., 2011; Schwartz et al., 2012; Li et al., 2013; Jiang et
47 al., 2013; Saide et al., 2013) DA algorithms. Ensemble-based DA algorithms, such as
48 the ensemble Kalman filter (EnKF) (Sekiyama et al., 2010; Schutgens et al., 2010a,
49 2010b; Pagowski and Grell, 2012; Dai et al., 2014; Rubin et al., 2016; Ying, X.M., et
50 al., 2016; Yumimoto et al., 2016) and the hybrid variational-ensemble DA approach
51 (Schwartz et al., 2014) have also been applied to aerosol predictions. All these studies
52 have shown that DA is one of the most effective ways of improving aerosol
53 forecasting through assimilating aerosol observations from multiple sources (e.g.
54 ground-based observations and satellite measurements) to update the chemical ICs.

55 Numerous studies have used DA approaches to estimate or improve source
56 emissions. The EnKF is one of the most popular DA algorithms used to improve
57 estimates of aerosols and gas-phase emissions, such as NO_x, volatile organic
58 compounds, and SO₂ (van Loon et al., 2000; Heemink and Segers, 2002; Zhang et al.,
59 2005; Barbu et al., 2009; Sekiyama et al., 2010; Huneus et al., 2012; Schutgens et al.,
60 2012; Huneus et al., 2012, 2013; Miyazaki et al., 2014). Variational DA algorithms

61 have also been applied to constrain emissions of air pollution, such as black carbon,
62 organic carbon, dust, NH_3 , SO_x and NO_x (Hakami et al., 2005; Elbern et al., 2007;
63 Henze et al., 2007, 2009; Yumimoto et al., 2007, 2008; Dubovik et al., 2008; Wang et
64 al., 2012; Guerrette and Henze, 2015). These studies have indicated that DA can
65 efficiently reduce the uncertainty in the emission inventories and lead to
66 improvements in the forecasting of air quality (Mijling and van der A, 2012).

67 The optimization of chemical ICs and pollution emissions can improve aerosol
68 forecasts and therefore further improvements are likely to be achieved by
69 simultaneously optimizing the chemical ICs and emissions. Tang et al. (2011)
70 reported that the simultaneous adjustment of the ICs of O_3 , NO_x and volatile organic
71 compounds and the emissions of NO_x and volatile organic compounds produced
72 overall better performance in both the 1-h and 24-h ozone forecasts than the
73 adjustment of pure ICs or emissions. Miyazaki et al. (2012) reported that the
74 simultaneous adjustment of emissions and concentrations is a powerful approach to
75 correcting the tropospheric ozone budget and profile analyses.

76 We developed a system to adjust the chemical ICs and source emissions jointly
77 within an EnKF system coupled to the Weather Research and Forecasting with
78 Chemistry (WRF-Chem) model (Grell et al., 2005). We then applied this system to
79 assimilate hourly surface $\text{PM}_{2.5}$ measurements over China in early October 2014.

80 The remainder of the paper is organized as follows. Section 2 describes this DA
81 system in detail and Section 3 describes the $\text{PM}_{2.5}$ observations. Then the
82 experimental designs are introduced in Section 4. Finally, the surface $\text{PM}_{2.5}$
83 observations assimilation results are presented in section 5 before concluding in
84 section 6.

85

86 **2. Methodology**

87 **2.1 Forecast model**

88 For a chemical model like WRF-Chem, the emissions are the model forcing (or
89 boundary condition), rather than model states. Therefore, a forecasting model, **M**,
90 was developed to forecast the emission scaling factors (representing emissions) as

91 well as the aerosol concentrations. This model combines the WRF-Chem model and
92 the forecast model of emission scaling factors.

93

94 2.1.1 WRF-Chem model

95 Version 3.6.1 of the WRF-Chem model (Grell et al., 2005) was used to forecast the
96 aerosol and chemical species. WRF-Chem is an online model with the fully coupled
97 chemical and meteorological components.

98 Most of the WRF-Chem settings were the same as those reported in Liu et al.
99 (2011): the Goddard Chemistry Aerosol Radiation and Transport (GOCART) aerosol
100 scheme coupled with the Regional Atmospheric Chemistry Mechanism for gaseous
101 chemical mechanisms; the WRF single-moment five-class microphysics scheme; the
102 Rapid Radiative Transfer Model longwave and Goddard shortwave radiation schemes;
103 the Yonsei University (YSU) boundary layer scheme; the Noah land surface model;
104 and the Grell-3D cumulus parameterization. For the GOCART aerosol scheme, the
105 aerosol species include 14 defined aerosol species and a 15th variable representing
106 unspatiated aerosol contributions (P_{25}). The 14 defined aerosol species are sulfate,
107 hydrophobic and hydrophilic organic carbon (OC_1 and OC_2 , respectively),
108 hydrophobic and hydrophilic black carbon (BC_1 and BC_2 , respectively), dust in five
109 particle size bins (effective radii of 0.5, 1.4, 2.4, 4.5 and 8.0 μm ; referred to as D_1 ,
110 D_2 , D_3 , D_4 and D_5 , respectively) and sea salt in four particle size bins (effective
111 radii of 0.3, 1.0, 3.25 and 7.5 μm for dry air; referred to as S_1 , S_2 , S_3 and S_4 ,
112 respectively).

113 Figure 1 illustrates the model computational domain. It has 120*120 horizontal
114 grid scales at a 40.5 km spacing by the Lambert conform map projection centered at
115 (35°N, 105°E). There are 57 vertical levels with the model top at 10 hPa, about 12
116 layers within the planetary boundary layer (among them the lowest 8 layers were
117 under 500 m), and the first layer centered at ~12 m.

118 With respect to the emissions, the hourly prior anthropogenic emissions were
119 based on the monthly regional emission inventory in Asia (Zhang et al., 2009) for the
120 year 2006 interpolated to the model grid. The power generator emissions were

121 interpolated for the lowest eight vertical levels (Woo et al., 2003; de meij et al., 2006;
 122 Wang et al., 2010). Other anthropogenic emissions were assigned totally to the 1st
 123 level. Emissions are very small above 500 m for all pollutants. In order to keep
 124 objective for the prior anthropogenic emissions, no time variation was added. Thus,
 125 the hourly prior anthropogenic emissions were constant. The biogenic (Guenther et al.,
 126 1995), dust (Ginoux et al., 2001), dimethylsulfide and sea salt emissions (Chin et al.,
 127 2000, 2002) were calculated online.

128

129 2.1.2 Forecast model of scaling factors

130 As no suitable dynamic model was available to forecast the emission scaling factors, a
 131 persistence forecasting operator served as the forecast model for the scaling factors,
 132 similar to the method used by Peng et al. (2015) for CO₂ emission inversion. Figure
 133 2a shows the flowchart for the persistence forecasting operator \mathbf{M}_{SF} .

134 If the ensemble members of the updated chemical fields $\mathbf{C}_{i,t-1}^a$ (the subscript i
 135 refers to the i th ensemble member, the superscript a refers to the analysis, and t
 136 refers to the time) and the forecast emissions $\mathbf{E}_{i,t-1}^f$ (the superscript f refers to the
 137 forecast) in the previous assimilation cycle are known, then the chemical fields $\mathbf{C}_{i,t}^f$
 138 at time t can be generated via WRF-Chem (Figure 2b). In the actual process, $\mathbf{C}_{i,t}^f$
 139 were available in the previous assimilation cycle, so we did not need to perform the
 140 ensemble forecasts again. A dotted box was used in Figure 2a to indicate that the
 141 ensemble forecasts were not performed in real process. The ensemble concentration
 142 ratios $\kappa_{i,t}$, ($i = 1, \dots, N$) are then calculated using

$$143 \quad \kappa_{i,t} = \frac{\mathbf{C}_{i,t}^f}{\overline{\mathbf{C}}_t^f}, (i = 1, \dots, N), (1)$$

144 where $\overline{\mathbf{C}}_t^f = \frac{1}{N} \sum_{i=1}^N \mathbf{C}_{i,t}^f$ is the ensemble mean of the forecast. The ensemble mean of
 145 $\kappa_{i,t}$ is,

$$146 \quad \overline{\kappa}_t = \frac{1}{N} \sum_{i=1}^N \kappa_{i,t} = \frac{1}{N} \sum_{i=1}^N \mathbf{C}_{i,t}^f / \overline{\mathbf{C}}_t^f = 1, (2)$$

147 so $\kappa_{i,t}$ are numbers distributed around 1 and with ensemble mean values of 1.

148 The ensemble spreads of $\kappa_{i,t}, (i = 1, \dots, N)$ may be small and therefore
 149 covariance inflation is used to maintain them at a certain level:

$$150 \quad (\kappa_{i,t})_{\text{inf}} = \beta(\kappa_{i,t} - \overline{\kappa_t}) + \overline{\kappa_t}, (i = 1, \dots, N), (3)$$

151 In Peng et al. (2015), the CO₂ DA system worked comparatively well when the
 152 ensemble spread of $\lambda_{i,t}^a$ ranged from 0.05 to 1.25 for $\beta = 60, 70, 75, 80$. The
 153 assimilated CO₂ fluxes deviated markedly from the “true” CO₂ fluxes when the
 154 ensemble spread of $\lambda_{i,t}^a$ were too small for $\beta = 10, 50$ or when the ensemble spread
 155 of $\lambda_{i,t}^a$ were too large for $\beta = 100$. Therefore, in this work, $\beta = 1.5$ was chosen to
 156 make ensure the ensemble spread of $(\kappa_{i,t})_{\text{inf}}$ ranged from 0.1 to 1.25. Same as $\kappa_{i,t}$,
 157 the ensemble mean values of $(\kappa_{i,t})_{\text{inf}}$ are 1. It is noted that perhaps there are very
 158 few negative values for $(\kappa_{i,t})_{\text{inf}}$ after inflation. A quality control procedure is
 159 performed for $(\kappa_{i,t})_{\text{inf}}$ before further appliance. All these negative data were set as
 160 0.001 in this work. There was no special reason to set them as 0.001. It is also fine to
 161 set them as 0. Then $(\kappa_{i,t})_{\text{inf}}$ were re-centered to ensure the ensemble mean values of
 162 $(\kappa_{i,t})_{\text{inf}}$ were all 1.

163 As the concentrations were closely related to the emissions both locally and in
 164 the upwind regions and there is no suitable dynamic model available to forecast the
 165 emission scaling factors, the inflated concentration ratios $(\kappa_{i,t})_{\text{inf}}$ serve as the prior
 166 emission scaling factors $\lambda_{i,t}^p$:

$$167 \quad \lambda_{i,t}^p = (\kappa_{i,t})_{\text{inf}}, (i = 1, \dots, N), (4)$$

168 The above equation is not supported according to the mass conservation equation
 169 but just for the purpose to generate the ensemble emissions. Same as $(\kappa_{i,t})_{\text{inf}}$, $\lambda_{i,t}^p$
 170 are numbers distributed around 1. From the perspective of generating the ensemble
 171 emissions, they can play the same role as other data, such as the random numbers
 172 created by using the standard normal distribution function. However, there are
 173 correlations among the grid-points of $(\kappa_{i,t})_{\text{inf}}$ because $(\kappa_{i,t})_{\text{inf}}$ are calculated

174 through a short-term forecast of WRF-Chem. Thus, $\lambda_{i,t}^p$ have the same correlations
 175 as $(\kappa_{i,t})_{\text{inf}}$. While, the random numbers are totally different. There are no
 176 correlations unless they are generated under certain correlations.

177 To incorporate the useful information from the previous times, the previous DA
 178 cycles' analysis scaling factors, $\lambda_{i,t-M+1}^a, \dots, \lambda_{i,t-2}^a, \lambda_{i,t-1}^a$ and the prior scaling
 179 factor $\lambda_{i,t}^p$ were used to estimate $\lambda_{i,t}^f$ by the time smooth operator; namely,

$$180 \lambda_{i,t}^f = \frac{1}{M} (\sum_{j=t-M+1}^{t-1} \lambda_{i,j}^a + \lambda_{i,t}^p), (i = 1, \dots, N, j = t - M + 1, \dots, t - 1), (5)$$

181 Here, M is the time window of the smooth operator. In this study, a value of $M = 4$
 182 (hours) was chosen. According to the smooth operator, the ensemble mean values of
 183 $\lambda_{i,t}^f$ depend on the ensemble mean of $\lambda_{i,t-M+1}^a, \dots, \lambda_{i,t-2}^a, \lambda_{i,t-1}^a, \lambda_{i,t}^p$, where the
 184 ensemble means of $\lambda_{i,t}^p$ are all 1. After multiple iterations, the smooth operator can
 185 give comparatively good estimation for $\lambda_{i,t}^f$ since anthropogenic emissions are stable
 186 at a certain time scale (Mijling et al., 2012). It is a compromise between prescribed
 187 prior emissions and letting the system propagate all observation information from one
 188 step to the next without any guidance (Peters et al., 2007), for the case $M = 4$.

189 The ensemble members of the emissions were calculated according to

$$190 \mathbf{E}_{i,t} = \lambda_{i,t} \mathbf{E}_t^p, (i = 1, \dots, N), (6)$$

191 where $\mathbf{E}_{i,t}$ is the i th ensemble member of the emissions for each grid at time t , $\lambda_{i,t}$
 192 represents the scaling factors and \mathbf{E}_t^p is the prescribed emission, which can be
 193 obtained from the emission inventories. It is noted that the correlations among the
 194 grid-points of the prior emissions depend on $\lambda_{i,t}^p$. These correlations may deviate far
 195 from the truth but we have no other suitable substitute. However, the correlations
 196 among the grid-points of the forecast emissions should be more or less close to the
 197 truth due to the appliance of the smooth operator after multiple iterations.

198 It is noted although the method is very similar to that used by Peters et al. (2007)
 199 and Peng et al. (2015) for CO₂ emission inversion, it is still of novelty for applications

200 in aerosol anthropogenic emissions. In Peters et al. (2007), $\lambda_{i,t}^p$ were all 1. And only
201 natural CO₂ emissions (i.e., biospheric and oceanic emissions) were assimilated at the
202 ecological scale due to the ‘signal-to-noise’ problem. Thus, the uncertainty of
203 anthropogenic and other CO₂ emissions were ignored. Besides, the framework is more
204 advanced compared to our previous work. In Peng et al. (2015), in order to generate
205 $\lambda_{i,t}^p$, a set of ensemble forecasts were performed from time t to $t+1$ to produce the CO₂
206 concentration fields, forced by the prescribed net CO₂ surface fluxes with the previous
207 assimilated concentration fields as initial conditions. That means that the ensemble
208 forecast were performed twice in that DA system and it was time consuming.
209 However, in order to save computing time, we used the chemical fields $C_{i,t}^f$ available
210 in the previous assimilation cycle to calculate $\lambda_{i,t}^p$ in this work. Thus, WRF-Chem
211 runs to forecast only once during a DA cycle.

212

213 **2.2 Ensemble square root filter**

214 The ensemble square root filter (EnSRF) algorithm was introduced by Whitaker
215 and Hamill (2002) and its expansion to analyzing aerosol ICs was described by
216 Schwartz et al. (2014). The traditional EnKF with perturbed observations (Evensen
217 1994) introduces sampling errors by perturbing the observations. In contrast to the
218 traditional EnKF, the EnSRF (Whitaker and Hamill, 2002) and the Ensemble
219 Adjustment Kalman Filter (EAKF, developed by Anderson, 2001) obviate the need to
220 perturb the observations. The local ensemble Kalman filtering (LEKF), a kind of
221 EnSRF, was presented by Ott et al. (2002, 2004). It was computationally more
222 efficient compared to the traditional EnKF, since it simultaneously assimilates the
223 observations within a spatially local volume independently. The local Ensemble
224 Transform Kalman Filter (LETKF, Hunt, 2007) integrates the advantages of the
225 Ensemble Transform Kalman Filter (ETKF, developed by Bishop et al., 2001) and the
226 LEKF. The computational cost of LETKF is much lower than that of the original
227 LEKF because the former does not require an orthogonal basis. Though LETKF has

228 more advantages, we still chose the same EnSRF as Schwartz et al. (2014) because we
 229 did not need to extend it to analyzing aerosol ICs, very similar to Schwartz et al.
 230 (2014).

231 Following the notation of Ide et al. (1997), given an m -dimensional background
 232 model forecast vector \mathbf{x}^b , a p -dimensional observation vector \mathbf{y}^o and an operator \mathbf{H}
 233 that converts the model state to the observation states, we expressed the variables as
 234 an ensemble mean (denoted by an over-bar) and a deviation from the mean (denoted
 235 by a prime). Thus, the ensemble mean $\bar{\mathbf{x}}^a$ of the analyzed state \mathbf{x}^a and the
 236 deviations \mathbf{x}'^a from the ensemble mean are updated separately by

$$237 \quad \bar{\mathbf{x}}^a = \bar{\mathbf{x}}^b + \mathbf{K}(\mathbf{y}^o - \mathbf{H}\bar{\mathbf{x}}^b), \quad (7)$$

$$238 \quad \mathbf{x}'^a = \mathbf{x}'^b + \tilde{\mathbf{K}}(\mathbf{y}'^o - \mathbf{H}\mathbf{x}'^b), \quad (8)$$

239 where \mathbf{K} is the traditional Kalman gain matrix and $\tilde{\mathbf{K}}$ is the gain used to update the
 240 deviations from the ensemble mean. These are given by

$$241 \quad \mathbf{K} = \mathbf{P}^b \mathbf{H}^T (\mathbf{H} \mathbf{P}^b \mathbf{H}^T + \mathbf{R})^{-1}, \quad (9)$$

$$242 \quad \begin{aligned} \tilde{\mathbf{K}} &= \mathbf{P}^b \mathbf{H}^T \left[\left(\sqrt{\mathbf{H} \mathbf{P}^b \mathbf{H}^T + \mathbf{R}} \right)^{-1} \right]^T \left(\sqrt{\mathbf{H} \mathbf{P}^b \mathbf{H}^T + \mathbf{R}} + \sqrt{\mathbf{R}} \right)^{-1} \\ &= \left(\mathbf{1} + \sqrt{\mathbf{R} / (\mathbf{H} \mathbf{P}^b \mathbf{H}^T + \mathbf{R})} \right)^{-1} \mathbf{K}, \quad (10) \end{aligned}$$

243 where $\mathbf{P}^b = \frac{1}{N-1} \sum_{i=1}^N \mathbf{x}'^b (\mathbf{x}'^b)^T$ is the $m * m$ -dimensional background error
 244 covariance matrix and \mathbf{R} is the $p * p$ -dimensional diagonal observation error
 245 covariance matrix. In real applications, $\mathbf{P}^b \mathbf{H}^T$ and $\mathbf{H} \mathbf{P}^b \mathbf{H}^T$ will be approximated
 246 using the background ensemble; namely,

$$247 \quad \mathbf{P}^b \mathbf{H}^T = \frac{1}{N-1} \sum_{i=1}^N \mathbf{x}'^b (\mathbf{H} \mathbf{x}'^b)^T \quad (11)$$

$$248 \quad \mathbf{H} \mathbf{P}^b \mathbf{H}^T = \frac{1}{N-1} \sum_{i=1}^N \mathbf{H} \mathbf{x}'^b (\mathbf{H} \mathbf{x}'^b)^T. \quad (12)$$

249 In equations (11) and (12), N is the ensemble size.

250 Note that for the joint analysis of ICs and emissions, the state vector \mathbf{x} is the
 251 joint vector of the mass concentration \mathbf{C} and the emission scaling factor $\boldsymbol{\lambda}$, i.e.
 252 $\mathbf{x} = [\mathbf{C}, \boldsymbol{\lambda}]^T$. In this study, the state variables of the analysis of the ICs were the 15
 253 WRF-Chem/GOCART aerosol variables, same as that reported by Schwartz et al.
 254 (2012). The state variables of the emission scaling factors include $\boldsymbol{\lambda}_{\text{PM}_{2.5}}$, $\boldsymbol{\lambda}_{\text{SO}_2}$, $\boldsymbol{\lambda}_{\text{NO}}$

255 and λ_{NH_3} and are described in section 2.3.1. After each ensemble analysis, the
256 ensemble forecasts were performed with the corresponding models to advance \mathbf{C} and
257 λ to the next analysis time.

258 In this work, a 50-member ensemble was chosen, following Schwartz et al.
259 (2012) and Whitaker and Hamill (2002). Covariance localization forced EnSRF
260 analysis increments to zero 1280 km from an observation in the horizontal and one
261 scale height to reduce spurious correlations due to sampling error for all control
262 variables, similar to Pagowski et al., (2012) and Schwartz et al., (2012, 2014). In
263 addition, posterior (after assimilation) multiplicative inflation following Whitaker and
264 Hamill (2012) was applied aiming to maintain ensemble spread for only the
265 concentration analysis. The inflation factor $\alpha = 1.2$ was chosen as Pagowski et al.,
266 (2012) and Schwartz et al., (2012, 2014). Additive or prior inflation was not employed.
267 As for the emission scaling factor λ , the inflation was not used at this step.

268

269 **2.3 Data assimilation system**

270 2.3.1 State variables

271 As stated in section. 2.2, the state variables of the analysis of the ICs were the 15
272 WRF-Chem/GOCART aerosol variables. The $\text{PM}_{2.5}$ observation operator was the
273 same as that described by Schwartz et al. (2012) and expressed as

$$274 \mathbf{y}^f = \rho_d [\mathbf{P}_{25} + 1.375\mathbf{S} + 1.8(\mathbf{OC}_1 + \mathbf{OC}_2) + \mathbf{BC}_1 + \mathbf{BC}_2$$
$$+ \mathbf{D}_1 + 0.286\mathbf{D}_2 + \mathbf{S}_1 + 0.942\mathbf{S}_2], (13)$$

275 where ρ_d represents the dry air density, which is multiplied by the mixing ratios of
276 aerosol species (in $\mu\text{g}\cdot\text{kg}^{-1}$) to convert the units to $\mu\text{g m}^{-3}$ for consistency with the
277 observations.

278 From the perspective of the optimization of emissions, four species of emission
279 scaling factors ($\lambda_{\text{PM}_{2.5}}$, λ_{SO_2} , λ_{NO} and λ_{NH_3}) were also considered as the state
280 variables of the DA system. Atmospheric inorganic aerosols are not only from the
281 primary emissions, but also from secondary processes- chemical and thermodynamic
282 transformations from the gas-phase precursors. Therefore, not only the primary
283 sources of $\text{PM}_{2.5}$, but also the sources of the gas-phase precursors, need to be

284 optimized. In this study, the sources of SO₂, NO_x and NH₃ (\mathbf{E}_{SO_2} , \mathbf{E}_{NO} and \mathbf{E}_{NH_3}),
 285 which have a large impact on the distribution of PM_{2.5}, were also optimized in
 286 addition to the primary sources of PM_{2.5}. It is noted that for the optimization of the
 287 emission scaling factors, \mathbf{M}_{SF} serves as the forecast model and the observation
 288 operator reflects the combined information of emissions (in the format of $\boldsymbol{\lambda}$ in
 289 equation (6)), the physics and chemistry processes in WRF-Chem simulations and the
 290 transformation PM_{2.5} from model space to observation space (equation (13)).

291 The direct sources of PM_{2.5} include the unspiciated primary sources of PM_{2.5}
 292 $\mathbf{E}_{\text{PM}_{2.5}}$, sulfate \mathbf{E}_{SO_4} , nitrate \mathbf{E}_{NO_3} , organic compounds \mathbf{E}_{org} and elemental
 293 compounds \mathbf{E}_{BC} ; all of them are given in two modes (the nuclei and accumulation
 294 modes, represented as i and j in the subscripts respectively). The ratios between the
 295 nuclei and accumulation modes were the same as in the suggested emission process
 296 for National Emission Inventory in WRF-Chem (Freitas et al., 2011). The formula of
 297 sulfate and nitrate emissions in the model are as below:

$$298 \quad \mathbf{E}_{\text{PM}_{2.5i}} : \mathbf{E}_{\text{PM}_{2.5j}} = 1 : 4, (14)$$

$$299 \quad \mathbf{E}_{\text{SO}_{4i}} : \mathbf{E}_{\text{SO}_{4j}} = 1 : 4, (15)$$

$$300 \quad \mathbf{E}_{\text{NO}_{3i}} : \mathbf{E}_{\text{NO}_{3j}} = 1 : 4, (16)$$

$$301 \quad \mathbf{E}_{\text{SO}_{4i}} + \mathbf{E}_{\text{SO}_{4j}} = a * (\mathbf{E}_{\text{PM}_{2.5i}} + \mathbf{E}_{\text{PM}_{2.5j}} - \mathbf{E}_{\text{EC}} - \mathbf{E}_{\text{ORG}}), (17)$$

$$302 \quad \mathbf{E}_{\text{NO}_{3i}} + \mathbf{E}_{\text{NO}_{3j}} = b * (\mathbf{E}_{\text{PM}_{2.5i}} + \mathbf{E}_{\text{PM}_{2.5j}} - \mathbf{E}_{\text{EC}} - \mathbf{E}_{\text{ORG}}), (18)$$

303 where \mathbf{E}_{EC} represents elemental carbon and \mathbf{E}_{ORG} organic compounds, and
 304 $a = 0.074$ and $b = 0.038$ were chosen based on the internal emissions and
 305 observational data. In the DA process, the first 6 species of direct sources of
 306 emissions ($\mathbf{E}_{\text{PM}_{2.5i}}$, $\mathbf{E}_{\text{PM}_{2.5j}}$, $\mathbf{E}_{\text{SO}_{4i}}$, $\mathbf{E}_{\text{SO}_{4j}}$, $\mathbf{E}_{\text{NO}_{3i}}$, and $\mathbf{E}_{\text{NO}_{3j}}$), which may have
 307 larger uncertainties in heavy polluted events, were updated according to the variation
 308 of $\boldsymbol{\lambda}_{\text{PM}_{2.5}}$. $\mathbf{E}_{\text{PM}_{2.5i}}$ and $\mathbf{E}_{\text{PM}_{2.5j}}$ were directly updated according to the variation in
 309 $\boldsymbol{\lambda}_{\text{PM}_{2.5}}$. The emissions ($\mathbf{E}_{\text{SO}_{4i}}$, $\mathbf{E}_{\text{SO}_{4j}}$, $\mathbf{E}_{\text{NO}_{3i}}$ and $\mathbf{E}_{\text{NO}_{3j}}$) were also updated according
 310 to the variations in $\mathbf{E}_{\text{PM}_{2.5i}}$ and $\mathbf{E}_{\text{PM}_{2.5j}}$.

311 \mathbf{E}_{EC} and \mathbf{E}_{ORG} of the anthropogenic emissions were not assimilated, which is a

312 limitation in this work. Besides, emissions of dust and sea salt were not assimilated. It
313 is true that these emissions are also important for the atmosphere aerosol. The reason
314 we did not assimilate \mathbf{E}_{EC} and \mathbf{E}_{ORG} is that only the $\text{PM}_{2.5}$ measurements are used in
315 this DA experiment. However, the sources of the aerosols (especially organic aerosols)
316 are so complex that our knowledge of their formation mechanisms is far from clear.
317 Though it is technically possible to have all emissions assimilated, with such limited
318 observations adding more control variables would cause much more uncertainties in
319 the system which might lead to unreasonable analysis.

320

321 2.3.2 Procedure for the DA system

322 Figure 2 (b) shows the workflow of the DA system. The steps in this workflow are as
323 follows.

324 (1) The persistence forecasting operator \mathbf{M}_{SF} is applied to forecast the
325 background fields of the emission scaling factors $\lambda_{\text{PM}_{2.5}}^f$, $\lambda_{\text{SO}_2}^f$, λ_{NO}^f and $\lambda_{\text{NH}_3}^f$. The
326 forecast chemical fields of P_{25} , SO_2 , NO and NH_3 of the previous assimilation cycle
327 are used to create the prior emission scaling factors $\lambda_{\text{PM}_{2.5}}^p$, $\lambda_{\text{SO}_2}^p$, λ_{NO}^p and $\lambda_{\text{NH}_3}^p$.
328 The background scaling factors are then generated using equation (5).

329 (2) The ensemble members of the emissions, $\mathbf{E}_{\text{PM}_{2.5}i}^f$, $\mathbf{E}_{\text{PM}_{2.5}j}^f$, $\mathbf{E}_{\text{SO}_2}^f$, \mathbf{E}_{NO}^f and
330 $\mathbf{E}_{\text{NH}_3}^f$, are prepared according to equation (6). The corresponding emissions of $\mathbf{E}_{\text{SO}_4i}^f$,
331 $\mathbf{E}_{\text{SO}_4j}^f$, $\mathbf{E}_{\text{NO}_3i}^f$ and $\mathbf{E}_{\text{NO}_3j}^f$ are obtained based on equations (15–18). Other inorganic
332 species of the anthropogenic emission, such as \mathbf{E}_{EC} and \mathbf{E}_{ORG} , are not perturbed for
333 WRF-Chem. However, other anthropogenic emissions, such as $\mathbf{E}_{\text{PM}_{2.5}}$, \mathbf{E}_{SO_4} and
334 \mathbf{E}_{NO_3} , are much larger than \mathbf{E}_{EC} and \mathbf{E}_{ORG} in most area of China, and the ensemble
335 spreads of the aerosol concentrate largely dependent on the uncertainties of those
336 anthropogenic emissions. Besides, model errors raised from the meteorology, the
337 emission and the chemical model itself are compensated to some extent through the
338 use of multiplicative inflation. In other words, the ensemble spread of the
339 concentrations can be kept at a certain level though \mathbf{E}_{EC} and \mathbf{E}_{ORG} , are not
340 perturbed.

341 Natural emissions, such as dust and sea salt emissions were not perturbed
342 explicitly when the forecast emissions were generated. However, emissions of dust
343 and sea salt were parameterized within the GOCART model (Chin et al., 2002).
344 Within the DA system, varying meteorology across the members implicitly perturbed
345 dust and sea salt emissions.

346 (3) Forced by the changed emissions ($\mathbf{E}_{\text{PM}_{2.5i}}$, $\mathbf{E}_{\text{PM}_{2.5j}}$, \mathbf{E}_{SO_2} , \mathbf{E}_{NO} , \mathbf{E}_{NH_3} ,
347 $\mathbf{E}_{\text{SO}_{4i}}$, $\mathbf{E}_{\text{SO}_{4j}}$, $\mathbf{E}_{\text{NO}_{3i}}$ and $\mathbf{E}_{\text{NO}_{3j}}$ were substituted by $\mathbf{E}_{\text{PM}_{2.5i}}^f$, $\mathbf{E}_{\text{PM}_{2.5j}}^f$, $\mathbf{E}_{\text{SO}_2}^f$, \mathbf{E}_{NO}^f ,
348 $\mathbf{E}_{\text{NH}_3}^f$, $\mathbf{E}_{\text{SO}_{4i}}^f$, $\mathbf{E}_{\text{SO}_{4j}}^f$, $\mathbf{E}_{\text{NO}_{3i}}^f$ and $\mathbf{E}_{\text{NO}_{3j}}^f$; the other emissions such as \mathbf{E}_{EC} and \mathbf{E}_{ORG}
349 remained unchanged), WRF-Chem is run again to forecast the chemical fields $\boldsymbol{\rho}^f$
350 with the updated chemical fields of the previous assimilation cycle as the ICs. The
351 state variables, i.e., 15 aerosol species and four scaling factors, are then prepared.

352 (4) The model-simulated $\text{PM}_{2.5}$ concentration at the observation space is then
353 calculated via equation (13). At this time, the state vector $\mathbf{x}^f = [\mathbf{C}^f, \boldsymbol{\lambda}^f]^T$ was
354 prepared.

355 (5) In the assimilation step, the state variables, the concentrations of 14 defined
356 aerosol species and a 15th unspiciated aerosol, and the four species of emission
357 scaling factors $\boldsymbol{\lambda}_{\text{PM}_{2.5}}^f$, $\boldsymbol{\lambda}_{\text{SO}_2}^f$, $\boldsymbol{\lambda}_{\text{NO}}^f$ and $\boldsymbol{\lambda}_{\text{NH}_3}^f$, were optimized through EnSRF.

358 (6) After the assimilation step, the optimized emissions ($\mathbf{E}_{\text{PM}_{2.5i}}^a$, $\mathbf{E}_{\text{PM}_{2.5j}}^a$, $\mathbf{E}_{\text{SO}_2}^a$,
359 \mathbf{E}_{NO}^a , $\mathbf{E}_{\text{NH}_3}^a$, $\mathbf{E}_{\text{SO}_{4i}}^a$, $\mathbf{E}_{\text{SO}_{4j}}^a$, $\mathbf{E}_{\text{NO}_{3i}}^a$ and $\mathbf{E}_{\text{NO}_{3j}}^a$) were calculated according to equations
360 (6, 15–18) using the optimized scaling factors ($\boldsymbol{\lambda}_{\text{PM}_{2.5}}^a$, $\boldsymbol{\lambda}_{\text{SO}_2}^a$, $\boldsymbol{\lambda}_{\text{NO}}^a$ and $\boldsymbol{\lambda}_{\text{NH}_3}^a$).

361

362 **3. $\text{PM}_{2.5}$ observation data and errors**

363 Hourly averaged surface $\text{PM}_{2.5}$ observations from the Ministry of Environmental
364 Protection of China were assimilated. There were altogether 876 national control
365 measurement sites over China. The $\text{PM}_{2.5}$ observation sites spanned most of central
366 and eastern China but were primarily located in urban and suburban areas. So it
367 always happened that there were more than one observation sites in certain city,
368 which were fall into the same model grid. Since we did not know the exact

369 observation environment of the sites, we randomly selected one observation site in a
370 city for assimilation experiment and one for verification purposes to ensure that there
371 was at most one assimilated measurements for one model grid. Altogether 77 stations
372 were selected for the PM_{2.5} assimilation experiment and another 77 independent
373 stations were selected for verification. Figure 1 shows the locations of 77
374 measurement sites used for the PM_{2.5} assimilation experiment and 77 independent
375 sites used for forecast verification.

376 The observation error covariance matrix \mathbf{R} in equation (9) includes
377 contributions from measurement and representation errors. Similar to the work of
378 Schwartz et al. (2012), the measurement error ε_0 is defined as $\varepsilon_0 = 1.5 + 0.0075 * \Pi_0$,
379 where Π_0 denotes the observational values for PM_{2.5} ($\mu\text{g m}^{-3}$). Thus, higher
380 PM_{2.5} values were associated with larger measurement errors. Following Elbern et al.
381 (2007) and Pagowski et al. (2010), Schwartz et al. (2012), the representativeness error
382 ε_r depends on the resolution of the model and the characteristics of the observation
383 locations and is calculated as $\varepsilon_r = r\varepsilon_0\sqrt{\Delta x/L}$, where r is an adjustable parameter
384 (here, $r = 0.5$), Δx is the grid spacing (here, 40.5 km), and L is the radius of
385 influence of an observation (here, L was set to 3 km following Elbern et al. (2007),
386 since we do not know the station type that used in this work). The total PM_{2.5} error (ε_t)
387 is defined as $\varepsilon_t = \sqrt{\varepsilon_0^2 + \varepsilon_r^2}$. The observation errors are assumed to be uncorrelated
388 so that \mathbf{R} is a diagonal matrix.

389 The PM_{2.5} observations were subject to quality control to ensure data reliability
390 before DA. Considering that China has had intense pollution events, PM_{2.5} values
391 larger than $800 \mu\text{g m}^{-3}$ were classified as unrealistic and were not assimilated;
392 observations with the ensemble mean of the first guess departure exceeding 100
393 $\mu\text{g m}^{-3}$ were also omitted, following Schwartz et al. (2012). The numbers of the
394 observations were about 17700. Among them 8 observations were discarded because
395 they were larger than $800 \mu\text{g m}^{-3}$ and 243 (around 1.5%) were discarded due to the
396 latter reasons.

397

398 **4. Experimental design**

399 Two parallel experiments were performed to evaluate the impact of PM_{2.5} DA on the
400 analyses and forecasts of aerosols over China: an assimilation experiment and a
401 control experiment. Both experiments used identical WRF-Chem settings and
402 physical parameterizations.

403

404 4.1 Spin-up ensemble forecast with perturbed Initial and boundary conditions

405 The initialization and spin-up procedures were identical to those reported by
406 Schwartz et al. (2014). The ICs and lateral boundary conditions (LBCs) for the
407 meteorological fields were provided by the National Centers for Environmental
408 Prediction Global Forecast System (GFS).

409 The initial meteorological fields were created at 0000 UTC 1 October 2014 by
410 interpolating the GFS analyses onto the model domain. The 50 ensemble members
411 were then generated by adding Gaussian random noise with a zero mean and static
412 background error covariances (Torn et al., 2006) to the temperature, water vapor,
413 velocity, geopotential height and dry surface pressure fields. The ICs of each member
414 were zero in the initial aerosol fields, representing clean conditions as described by
415 Liu et al. (2011).

416 The LBCs for the meteorological fields were then interpolated from the GFS
417 analyses from 0000 UTC 1 October 2014 to 0000 UTC 16 October 2014 and
418 perturbed similarly to the initial fields at 0000 UTC 1 October 2014. The aerosol
419 LBCs of each member for all experiments were idealized profiles embedded within
420 the WRF/Chem model.

421 Fifty-member emissions were created by adding random noise to the
422 anthropogenic emissions, same as reported by Schwartz et al. (2014),

$$\mathbf{E}_{ip}^*(\eta, t) = \mathbf{E}_p(\eta, t) + \mathbf{W}_{ip} \boldsymbol{\sigma}_p^E(\eta, t)$$

423 where $\mathbf{E}_{ip}^*(\eta, t)$ is the i th ensemble member for the p th emissions variable at the
424 η th grid point and the t th hour, \mathbf{E}_p is the unperturbed emissions. The term $\boldsymbol{\sigma}_p^E$ is

425 the standard deviation of all \mathbf{E}_p values and in the horizontally adjacent points of grid
426 box η at and within 2 h of t . \mathbf{W} is a weight that was randomly drawn from a
427 standard Gaussian distribution and varied for each ensemble member and variable but
428 was spatially and temporally constant. No correlations between emissions variables
429 were considered, which was a limitation of this approach. For possible negative
430 perturbed emissions, they were set as $\mathbf{E}_{ip}^*(\eta, t) = 0.001 * \mathbf{E}_p(\eta, t)$. This will increase
431 the prescribed emissions more or less. However, only very few data were negative. So,
432 this influence can be negligible.

433 Before the first DA cycle, a 50-member ensemble of four-day WRF-Chem
434 forecasts was performed from 0000 UTC 1 October to 2300 UTC 4 October 2014
435 using the perturbed ICs at 0000 UTC 1 October 2014, the corresponding perturbed
436 LBCs and the emissions. Then a 50-member ensemble aerosol forecasts at 0000 UTC
437 5 October 2014 were produced.

438

439 4.2 Assimilation experiments

440 Two DA experiments were performed. One was the pure assimilation of chemical ICs
441 (hereafter expC), the others was the joint adjustment of chemical ICs and source
442 emissions (hereafter expJ). Both DA experiments had same settings except for the
443 emissions. They were conducted from 0000 UTC 5 October 2014 to 0000 UTC 16
444 October 2014. The assimilation cycle interval was 1 h.

445 In the first DA cycle in expJ, the first 50 ensemble chemical fields were drawn
446 from the WRF-Chem ensemble forecasts valid at 0000 UTC 5 October 2014, as
447 described in section 4.1. Using the ensemble aerosol forecasts, the prior emission
448 scaling factors $\lambda_{i,t}^p$ at 2300 UTC 4 October 2014 were calculated. $\lambda_{i,t}^p$ were used
449 directly as $\lambda_{i,t}^f$ for the first 5 assimilation cycles (after 5 assimilation cycles, the
450 system has been initialized, all future scaling factors could be created using the
451 persistence forecasting operator \mathbf{M}_{SF}). Then, the state vector $\mathbf{x}^f = [\mathbf{C}^f, \boldsymbol{\lambda}^f]^T$ was
452 prepared. And after that, the DA cycle started.

453 In expC, the first chemical fields were also drawn from the WRF-Chem

454 ensemble forecasts valid at 0000 UTC 5 October 2014. Then, the state vector
455 $\mathbf{x}^f = [\mathbf{C}^f]^T$ was prepared and the DA cycle started.

456 At the WRF-Chem forecast step of the subsequent assimilation cycles for both
457 experiments, the ICs for the chemical variables of each member were drawn from the
458 updated chemical fields of the previous cycle. The aerosol LBCs of each member for
459 all experiments were idealized profiles embedded within the WRF/Chem model. As
460 for the meteorological ensemble fields, the LBCs were prepared in advance as
461 depicted in section 4.1; the ICs of each member of the meteorological fields were
462 drawn from the forecast meteorological fields of the previous cycle before
463 re-centering with the GFS analysis because we do not do meteorological analysis:

$$464 \quad \boldsymbol{\pi}_{i_{\text{new}}} = \boldsymbol{\pi}_i + (\boldsymbol{\pi}_{\text{GFS}} - \bar{\boldsymbol{\pi}}), (18)$$

465 where $\boldsymbol{\pi}_i$ is the i th member of the forecast meteorological fields of the previous
466 cycle, $\bar{\boldsymbol{\pi}}$ is the ensemble mean of the forecast meteorological fields of the previous
467 cycle, $\boldsymbol{\pi}_{\text{GFS}}$ is the meteorological field interpolated from the GFS analyses and
468 $\boldsymbol{\pi}_{i_{\text{new}}}$ is the new meteorological field used as the IC in WRF-Chem in the next cycle.

469 As stated in the first paragraph in this section, the settings of expC were the same
470 as those in expJ except for the emissions. In expJ, the ensemble anthropogenic
471 emissions were generated by using emission scaling factors. While in expC, the
472 ensemble anthropogenic emissions were prepared by adding random noise, as stated
473 in 4.1.

474

475 4.3 Control experiment

476 The control experiment was conducted for the same period as the assimilation
477 experiment and the simulation cycle period was 1 h, as in the assimilation experiment.
478 The first initial chemical fields were extracted from the ensemble mean valid at 0000
479 UTC 5 October 2014. In the subsequent simulation process, the ICs for the chemical
480 fields were from the previous cycle's 1-h forecast. The LBCs and ICs for the
481 meteorological fields were updated by interpolating the GFS analyses. The emissions
482 were the prescribed emissions \mathbf{E}_t^p without any perturbation.

483

484 **5. Results**

485 Statistics for both expJ and expC were computed using the ensemble mean prior
486 (background) and posterior (analysis) fields (average of the 50-member ensemble).
487 The ensemble performances were first examined. Output from the first day of the
488 cycling DA configurations was excluded from all verification statistics to allow the
489 ensemble fields to “spin up” from the initial ensemble.

490 As the measurement coverage is an important factor that may determine the
491 performance in DA, we primarily focused our attention on the results from three
492 sub-regions with comparatively dense observational coverage (Figure 1): the Beijing–
493 Tianjin–Hebei region (JJJ, 12 stations for assimilation and 12 stations for verification);
494 the Yangtze River delta (YRD, 24 stations for assimilation and 24 stations for
495 verification); and the Pearl River delta (PRD, 9 stations for assimilation and 9 stations
496 for verification).

497

498 5.1 Ensemble performance

499 It is important to assess the ensemble performance for an ensemble-based DA system.
500 In a well-calibrated system, a comparison of the prior ensemble mean
501 root-mean-square error (RMSE) with respect to the observations should equal the
502 prior “total spread” (square root of the sum of ensemble variance and observation
503 error variance) (Houtekamer et al., 2005). Figure 3 shows the time series for the prior
504 ensemble mean RMSE and the total spread for PM_{2.5} aggregated over all observations
505 in the three sub-regions for expJ. It indicates that the magnitudes of both the total
506 spread and the RMSE were influenced by the diurnal cycle and heavy air pollution.
507 Almost all the total spreads were smaller than the RMSE, showing an insufficient
508 spread of PM_{2.5} ensemble forecasts, which is especially evident for heavy polluted
509 period with much larger RMSEs. For expC, the characteristics of the prior ensemble
510 mean RMSE and the total spread for PM_{2.5} were very similar to that for the joint DA
511 experiment.

512 The magnitudes of the ensemble spread of the emission scaling factors of the

513 joint DA experiment were important for emission inversion. They were very stable
514 throughout the ~10 day experiment period, which indicates that \mathbf{M}_{SF} can generate
515 stable artificial data to generate the ensemble emissions. For $\lambda_{\text{PM}_{2.5}}^f$, they ranged
516 from 0.25 to 1 in most model area. Figure 3d shows the area-averaged time series
517 extracted from the ensemble spread of $\lambda_{\text{PM}_{2.5}}^f$. It shows that the ensemble spread was
518 stably distributed around 0.5, which indicates that the uncertainty of the ensemble
519 emissions was about 50%.

520

521 5.2 Impact on aerosol ICs

522 To evaluate quantitatively the impact of the ensemble assimilation system on the ICs,
523 the mean errors (bias), RMSEs and correlation coefficient (CORR) of the assimilation
524 experiment and the control run were first analyzed. These statistics were calculated
525 against independent observations over all the analyses from 6 to 16 October 2014.
526 Table 1 shows that the bias magnitudes of the control run were 15.9 and 20.6 $\mu\text{g m}^{-3}$
527 for the YRD and the PRD, respectively, suggesting a significant overestimation of the
528 WRF-Chem aerosol mass in these two sub-regions. However, a significant
529 underestimation of the aerosol mass occurred in the JJJ region, where the model bias
530 was $-18.0 \mu\text{g m}^{-3}$. The RMSEs of the control run were 81.6, 30.6 and 31.8 $\mu\text{g m}^{-3}$ for
531 the JJJ, YRD and PRD regions, respectively. After assimilation, the statistics showed
532 an apparent improvement and the magnitude of the bias and the RMSE decreased for
533 both DA experiment. For expJ, both the maximum bias and the RMSE were obtained
534 in the JJJ region, and were -10.3 and $66.9 \mu\text{g m}^{-3}$, respectively. The CORR increased
535 from 0.79, 0.60, and 0.62 to 0.83, 0.85, and 0.80 for the JJJ, YRD and PRD,
536 respectively. The statistics of expC were very similar to those of expJ. The bias and
537 the RMSE in the JJJ region were -12.2 and $64.0 \mu\text{g m}^{-3}$, respectively. And the CORR
538 were 0.85, 0.80, and 0.80 for the JJJ, YRD and PRD, respectively. These results
539 indicate that the initial $\text{PM}_{2.5}$ fields can be adjusted efficiently by the EnSRF.

540 It is interesting to note that expC has better RMSE and CORR than expJ but poor
541 bias in JJJ. And expC has better bias and RMSE than expJ but poor CORR in PRD.
542 Maybe small number of samples caused the uncertainties of the statics. However, the

543 differences were very small. The analysis of both experiments were very similar.

544 Then the analysis increments (i.e. $\bar{\mathbf{x}}^a - \bar{\mathbf{x}}^b$) were investigated to show the direct
545 impact of PM_{2.5} DA. They are determined by both the observation increments and the
546 relative magnitudes of the forecast error and the observation error, based on Equation
547 (7). From Figure 4(a), (e) and (f), the increments of both assimilation experiments
548 were distributed around the observations as expected. However, the impact of
549 assimilating PM_{2.5} observations was not limited to the areas where observations were
550 located, observations information was also transported to other areas through the
551 WRF-Chem forecast. Besides, the ensemble forecasts also partly contributed to the
552 spatial distribution of the PM_{2.5} mass. Therefore, the spatial distributions of the PM_{2.5}
553 mass in both assimilation experiments were significantly different from the control
554 run (see Figure 4(b), (c) and(d)), which suggest that assimilation PM_{2.5} observations
555 impacts greatly on the aerosol ICs. The PM_{2.5} mass magnitude of both assimilation
556 experiments were smaller than that of the control run at the lowest model level in the
557 YRD, the PRD and in central China. Conversely, positive differences (analysis minus
558 control) were gained in the JJJ region and in northeast China. These indicated the
559 reduction of the overestimation or underestimation of the WRF-Chem simulation over
560 these regions with data assimilation.

561

562 5.3 Impact on emissions

563 To determine the impact of assimilating PM_{2.5} observations on the chemical emissions,
564 we analyzed the area-averaged time series extracted from the forecast emission
565 scaling factors, the optimized emission scaling factors, the prior emissions and the
566 optimized emissions. Figure 5 shows that $\lambda_{\text{PM}_{2.5}}^f$ were changed along with $\lambda_{\text{PM}_{2.5}}^a$.
567 This indicates that observation information ingested from the previous observations
568 was incorporated through the usage of the time smooth operator.

569 Figure 5 also shows that although the prior emissions $\mathbf{E}_{\text{PM}_{2.5}}^p$ had no diurnal
570 variation when the experiments were designed, the optimized PM_{2.5} scaling factor,
571 $\lambda_{\text{PM}_{2.5}}^a$, showed an obvious variation with time, as did the optimized unspiciated

572 primary sources of $\text{PM}_{2.5}$, $\mathbf{E}_{\text{PM}_{2.5}}^{\text{a}}$. Moreover, the values of $\lambda_{\text{PM}_{2.5}}^{\text{a}}$ were <1 at almost
573 all times in the YRD and PRD, which resulted that the analyzed emission $\mathbf{E}_{\text{PM}_{2.5}}^{\text{a}}$
574 were lower than the prior $\text{PM}_{2.5}$ emissions $\mathbf{E}_{\text{PM}_{2.5}}^{\text{p}}$. In the YRD, the prior $\mathbf{E}_{\text{PM}_{2.5}}^{\text{p}}$ was
575 about $0.127 \mu\text{g m}^{-2} \text{s}^{-1}$ over all hours. After assimilation, the time-averaged optimized
576 $\mathbf{E}_{\text{PM}_{2.5}}^{\text{a}}$ decreased to $0.107 \mu\text{g m}^{-2} \text{s}^{-1}$, about 15.6% lower than the prior value. In the
577 PRD, the prior $\mathbf{E}_{\text{PM}_{2.5}}^{\text{p}}$ was about $0.10 \mu\text{g m}^{-2} \text{s}^{-1}$. The time-averaged optimized
578 $\mathbf{E}_{\text{PM}_{2.5}}^{\text{a}}$ decreased to $0.066 \mu\text{g m}^{-2} \text{s}^{-1}$, leading to a decrease of 35.0%. However,
579 larger values for the optimized $\mathbf{E}_{\text{PM}_{2.5}}^{\text{a}}$ were obtained in the JJJ region in three
580 periods, from 1600 UTC 6 October to 0000 UTC 8 October, from 1600 UTC 9
581 October to 0000 UTC 10 October, and from 1600 UTC 13 October to 0000 UTC 15
582 October as a result of the increased optimized scaling factor $\lambda_{\text{PM}_{2.5}}^{\text{a}}$. This may have
583 been caused by the burning of crop residues during harvesting in this region (Li et al.,
584 2016), which was not taken into account in the prior emissions. However, the $\text{PM}_{2.5}$
585 measurements network was still spatially sparse and heterogeneous in this work.
586 Almost all measurements were located in the city and no data available in the rural.
587 Meanwhile, the crop residues burning always occur in the rural region. Therefore, the
588 $\text{PM}_{2.5}$ measurements network can only capture the burning information a few hours
589 later. Hence, although the system is able to detect the emission changes caused by
590 burning events, the time that the system started to show increased scaling factors
591 might be not accurate enough (may shift a few hours later). Maybe a Kalman
592 smoother would have been a better system to solve this problem.

593 The NO , SO_2 and NH_3 emissions were all adjusted to some extent by our DA
594 approach (see Figure 6). The NO emissions increased by 41.3, 43.7 and 20.3% in the
595 JJJ, YRD and PRD regions, respectively. The SO_2 emissions increased by 16.3, 10.0
596 and 18.3% and the NH_3 emissions increased by 16.7, 7.8 and 7.5% in the JJJ, YRD
597 and PRD regions, respectively.

598 Figure 7 shows the spatial distribution of the time-averaged scaling factors
599 $\lambda_{\text{PM}_{2.5}}^{\text{a}}$ at the lowest model level over all hours from 6 to 16 October 2014, since the
600 emissions at higher levels were so small that the impact of assimilating $\text{PM}_{2.5}$

601 observations was negligible. Figure 8 shows the distribution of $E_{PM_{2.5}}^p$ and the
602 time-averaged differences between the ensemble mean of the assimilation and the
603 prior values.

604 These patterns are consistent with those in Figure 5. Negative differences were
605 obtained in most areas of the YRD and PRD, indicating that the $PM_{2.5}$ DA primarily
606 decreased the $PM_{2.5}$ emissions. Conversely, positive differences were obtained in
607 South Hebei, North Henan and Southeast Shanxi provinces, indicating that DA
608 increased the $PM_{2.5}$ emissions.

609 As the economy in China has developed, the spatiotemporal distribution of
610 emissions has changed as a result of changes in energy consumption, the structure of
611 the energy market and advances in technology. Therefore although this inventory of
612 emissions may have correctly described anthropogenic emissions in 2006 when it was
613 constructed, it is not representative of the anthropogenic emissions in 2014.
614 Theoretically, the assimilated emissions should reduce the uncertainty in the prior
615 emissions as a result of the application of observations. Different from the situations
616 that standard national emission inventories were reported by government in USA,
617 European or other countries, the rapid economic development and complexity of
618 emission sources in China lead to large uncertainties in the current emission
619 inventories even for the latest version. Thus it's impossible for us to conduct the direct
620 evaluation on emissions.

621 Although we had no direct emission observations to evaluate the analyzing
622 emissions, which was a challenging to many emission inversion research teams (e.g.
623 Tang et al, 2011; Miyazaki et al., 2012; Ding et al., 2015; Mclinden et al., 2016; etc.),
624 the improvement of emissions can be verified in terms of two aspect, the diurnal
625 variation and the location of increased emissions. The diurnal variation in the
626 assimilated emissions verified this statement to some extent. Especially in the PRD
627 and YRD, $E_{PM_{2.5}}^a$ in the daytime were always larger than those in the night, which
628 agreed well with Olivier et al. (2003), the WRAP (2006) and Wang et al. (2010). In
629 addition, the locations of the larger values for the optimized $E_{PM_{2.5}}^a$ in the JJJ region

630 was in good agreement with the place of the crop residues burning *traced by the*
631 environmental satellite of China. There were 10, 231, 37 and 3
632 crop residue burning spots in Hebei, Henan, Shandong and Shanxi province
633 respectively from 5 to 11 October 2014 and 7, 20, 5 and 21 respectively from 12 to 18
634 October 2014 (Weekly Crop Residue Burning Monitoring Report traced by
635 Environmental Satellite, 2015a, 2015b).

636 However, the analysis emissions are only a mathematical optimum. They are
637 influenced greatly by the model errors and the observation errors. In addition, only
638 surface PM_{2.5} observations were applied in this work, which may lack abundant
639 constraint on the sources of the secondary aerosol precursors. More observations are
640 needed to obtain reliable emissions for the sources of the gas-phase precursors.

641

642 5.4 Verification of aerosol forecasting

643 For the assimilation experiment, 48-h forecasts were performed at each 0000
644 UTC from 6 to 16 October 2014 with the hourly forecast output for both assimilation
645 experiments. For the verification forecasting experiment for expJ (hereafter fcJ), the
646 ensemble mean of the analyzed ICs and emissions of expJ were used in this
647 longer-range model forecast. For the verification forecasting experiment for expC
648 (hereafter fcC), the ensemble mean of the analyzed ICs of expC and the prescribed
649 anthropogenic emissions were used.

650 In order to get a more visualized picture of the impact of DA for both
651 assimilation experiments, time series of the hourly PM_{2.5} extracted from the analysis
652 (AN), the control run (CT) and the hourly output of 48-h forecast (fc24 for the first
653 day forecast and fc48 for the second day forecast) were compared with the
654 observations (OBS) for three megacities Beijing, Shanghai and Guangzhou,
655 respectively (Figure 9). As expected, the time series of the analysis (also the
656 background) were consistent with the observations. The control run showed large
657 deviations from the observations, especially in Shanghai and Guangzhou. Benefit
658 from DA on both the first day and the second day forecasts can be clearly seen.

659 The bias and the RMSE of the surface PM_{2.5} forecasts as a function of forecast

660 range was then calculated against the independent observations for the three
661 sub-regions (Figure 10). Both the bias and the RMSEs of the control run were
662 characterized by the diurnal cycle in the YRD and PRD. The largest errors were seen
663 at 2100 UTC in the YRD (about $29 \mu\text{g}\cdot\text{m}^{-3}$ for bias and $37 \mu\text{g}\cdot\text{m}^{-3}$ for RMSEs) and at
664 2300 UTC in the PRD (about $36 \mu\text{g}\cdot\text{m}^{-3}$ for bias and $41 \mu\text{g}\cdot\text{m}^{-3}$ for RMSEs), likely
665 indicating significant systematic forecast errors at these times. From 0300 to 0900
666 UTC, the bias (about $1 \mu\text{g}\cdot\text{m}^{-3}$ in the YRD and $-5 \mu\text{g}\cdot\text{m}^{-3}$ in the PRD) and the RMSE
667 values (about $14 \mu\text{g}\cdot\text{m}^{-3}$ in the YRD and $16 \mu\text{g}\cdot\text{m}^{-3}$ in the PRD) were much smaller
668 than at other times in both the YRD and PRD, showing that WRF-Chem performed
669 well during this period. However, in the JJJ region, the bias (about $-20 \mu\text{g}\cdot\text{m}^{-3}$) and
670 the RMSEs (about $50 \mu\text{g}\cdot\text{m}^{-3}$) were always large as a result of a heavy pollution event.
671 After assimilation, both the magnitude of the bias and the RMSEs decreased sharply.
672 Especially in in YRD and PRD, most bias ranged from -5 to $5 \mu\text{g}\cdot\text{m}^{-3}$ and most
673 RMSEs ranged from 11 to $14 \mu\text{g}\cdot\text{m}^{-3}$, further indicating that DA greatly affected the
674 ICs.

675 The improvements in the surface $\text{PM}_{2.5}$ forecasts by the joint adjustment of the
676 ICs and emissions were very large in the YRD and PRD for expJ. Large reduction of
677 the magnitude of the bias and the RMSEs due to assimilation can be seen for almost
678 the entire 48-h forecast range. From 10- to 23-h and from 34- to 47-h, in particular,
679 the relative reduction in RMSE was about 37.5%. However, the DA impact was much
680 smaller for 3- to 9-h forecast ranges, which are at daytime of the first day forecast. In
681 addition, the improvements were nearly negligible in PRD from 27- to 33-h, the
682 daytime of the second day forecast, suggesting that the benefit gained from adjusting
683 the ICs decreased progressively and eventually disappeared with model integration.
684 And the performance was actually deteriorated in YRD during the same time. One of
685 the possible reasons was that chemical model performed sufficiently well during
686 daytime when the boundary layer was unstable and therefore the further improvement
687 was more difficult. And there were always large errors during the night when the
688 boundary layer was stable, so that large improvements could be obtained. The other
689 possible reason can be attributed to the a priori constant emissions. The differences

690 between the optimized $PM_{2.5}$ emissions and the prior emissions were comparatively
691 small during the day, but the optimized $PM_{2.5}$ emissions were much smaller than the a
692 prior emissions during the night. So that the control run could performed worse during
693 the night and it could performed well during the day. Given the a priori variable
694 emissions provided, the control run will perform better during the night. Nevertheless,
695 attributed greatly to the large adjustment of chemical emissions, substantial
696 improvements were still achieved from 34- to 47- h. These results revealed that joint
697 adjustment of the ICs and emissions can improve surface $PM_{2.5}$ forecasts up to 48 h in
698 the YRD and PRD.

699 As for expC, it seemed that large improvements in the surface $PM_{2.5}$ forecasts
700 were gained through the adjustment of the ICs in PRD from 10- to 23-h and from 34-
701 to 47-h. Large reduction of the magnitude of the bias and the RMSEs due to
702 assimilation can be seen during this period. The relative reduction in RMSE ranged
703 from 25% to 37.5%. However, the forecasts deviated much from the observations for
704 3- to 9-h and 27- to 33-h forecast ranges. One of the reason may be that the
705 adjustment of the ICs decreased the analysis field too much on the whole since the
706 WRF-Chem forecast aerosol mass was systematically overestimated in PRD (see
707 Figure 4, Figure 9f and Figure 10e). While this aerosol mass overestimation might be
708 also due to the possibly overestimated emissions in some time periods (not all-day
709 long) which are not corrected in the simulation. So the over-adjusted ICs compensated
710 the unadjusted emissions in some period but also lead to the negative biases for the
711 periods when emission is not overestimated or underestimated. The other factor was
712 the diurnal variation. It is very clear that $PM_{2.5}$ mass gradually decreased with time
713 from 0000 UTC to 0008 UTC and then obtained the smallest value. After that it
714 increased with time from 0009 UTC to 0023 UTC obtained the largest value at about
715 0000 UTC. Both reasons led to the systematically underestimation of $PM_{2.5}$ mass of
716 fcC from 3- to 9-h and from 27- to 33-h, though maybe the aerosol ICs were very
717 close to the observations. Therefore, both the magnitude of the bias and the RMSEs of
718 the fcC were larger than those of the control run. In addition, $PM_{2.5}$ forecasts of the
719 fcC were benefit much from the diurnal variation and the adjustment of the ICs from

720 10- to 23-h and from 34- to 47-h. As a consequence, the magnitude of the
721 corresponding bias and the RMSEs of the fcC were smaller than those of the control
722 run. Similar statics characteristics were also gained in YRD. But the improvements
723 were comparatively small from 10- to 23-h and from 34- to 47-h. However, the
724 performance of fcJ was much better than that of fcC during the night in PRD and
725 YRD. While in the daytime, the improvement of expJ seems to be not so big or even
726 negligible. This could be attributed much to the emissions since the ICs of both
727 forecasts were very similar. In the forecast experiment of expC, the emissions were
728 the default monthly anthropogenic emissions. While in the forecast experiment of
729 expJ, the assimilated emissions were much smaller than the default anthropogenic
730 emissions in almost all the night in both regions indicating that the prior emission
731 uncertainties might be the dominating reasons that cause biases between observed and
732 model simulated concentrations in these cases. In the daytime in PRD, the assimilated
733 emissions were a little smaller than the default anthropogenic emissions. But in the
734 daytime in YRD, the assimilated emissions were a little larger than the default
735 anthropogenic emissions for most time (see Figure 5). While those changes between
736 assimilated emissions and prior emissions in the daytime are not as significant as that
737 in the nighttime.

738 Both DA systems did not perform as well in the JJJ region as in the YRD and
739 PRD. Relatively smaller improvements were achieved in the first 24-h forecast but
740 then no improvements were achieved afterwards in JJJ. One possible reason for this
741 result may be systematic errors due to chemistry mechanism in WRF-Chem. The
742 sources of the aerosols are so complex that our knowledge of their formation
743 mechanisms is far from clear and large uncertainties still exist in the model
744 simulations. Chemical transport models have a tendency to underestimate PM
745 concentrations, especially during episodes of heavy pollution (Denby et al., 2007) due
746 to some missing reactions (Wang et al., 2014; Zhang et al., 2015, Zheng et al., 2015;
747 Chen et al., 2016). Another reason can be attributed to the forecast meteorological
748 fields. There were still large uncertainties, especially when boundary layer was stable
749 and the wind speed was very small during episodes of heavy pollution. As a result, a

750 large bias may be obtained in forecasts of heavy pollution given the ICs and emission
751 inventories achieved from the joint assimilation. Another reason may be the sparse
752 coverage of measurements. There were only 12 sites in the JJJ region (Figure 1) and
753 the measurement coverage was much sparser than in the YRD or PRD.

754

755 **6. Summary and Discussion**

756 The EnSRF algorithm was extended to adjust the chemical ICs and the primary
757 and precursor emissions to improve forecasts for surface PM_{2.5}. This system was
758 applied to assimilate hourly surface PM_{2.5} measurements from 5 to 16 October 2014
759 over China. To evaluate the effectiveness of DA, 48-h forecasts were performed using
760 the optimized ICs and emissions, together with a control experiment without DA.
761 Besides, the experiment of pure assimilation chemical ICs and the corresponding 48-h
762 forecasts experiment were also performed for comparison. The results indicated that
763 the forecasts with the optimized ICs and emissions performed much better than the
764 control simulations. Large improvements were achieved for almost all the 48-h
765 forecasts, particularly in the YRD and PRD. However, it did show some
766 improvements in the first 24-h but then there is no difference between the control run
767 and the forecasts in the JJJ region afterwards, which may be attributed to the sparse
768 measurement coverage and the deficiencies in the model system for forecasting heavy
769 pollution. Comparing to the forecasts with only the optimized ICs, the forecasts with
770 the joint adjustment were always much better during the night in the PRD and YRD
771 regions. However, they were very similar during daytime in both regions. And in the
772 JJJ region, they performed similarly for almost the entire 48-h forecast range.

773 There are still some limitations in this study. Firstly, we use the default monthly
774 anthropogenic emissions as the prior emissions and no time variation was added to
775 keep objective, since no resolution of temporal allocations at shorter but critical
776 (e.g., day-of-week, diurnal) scales is available. As shown in earlier work, the constant
777 emissions will worsen the chemical forecasts (de Meij et al., 2006; Wang et al, 2009).
778 For the joint DA system itself, it cannot benefit from the constant prior anthropogenic
779 emissions. But the normalized RMSE in Figure 10g decreased due to the poor

780 forecasts of control run. The control run will perform better when variable emissions
781 within the day are allowed, especially during the night. As a result, the relative
782 reduction in RMSE could not be so large during the night. Secondly, no correlations
783 between emissions variables were considered when perturbing the emissions, which
784 will lead to the reduction of the correlations between the variables. Thus, the chemical
785 forecast will deviate from the truth to some degree. Fortunately, the perturbed
786 emissions were only used in the initialization and spin-up experiment and expC.
787 Therefore, there were no impacts on expJ and the control run except for expC. Thirdly,
788 E_{EC} and E_{ORG} are not perturbed in expJ. However, as stated in Sect. 2.3.2, the
789 ensemble spread of OC_1 and OC_2 can be kept at a certain level. As a result, OC_1
790 and OC_2 changed much contributed to the $PM_{2.5}$ assimilation in expJ, which
791 suggests that the influence of not perturbing E_{EC} and E_{ORG} could be negligible. But,
792 because of the too small magnitudes of BC_1 and BC_2 , the differences (assimilation
793 minus control) of BC_1 and BC_2 were nearly close to zero. Fourthly, the experiment
794 (expE) where only emissions were assimilated was not included here. But it was still
795 worth to simultaneously assimilate the chemical ICs and emission. For one thing, in
796 expE, the chemical concentrations can be updated by the WRF-Chem model
797 simulations with the assimilated emissions as the initial field in each DA cycle. That
798 means that the 50-member ensemble forecasts were performed twice and it was time
799 consuming. For another, better concentration analysis could be obtained in expJ due
800 to the simultaneous assimilation of ICs and emissions. While in expE, there may be
801 larger uncertainties for the updated chemical concentrations through WRF-Chem due
802 to the deficiency of chemistries and the uncertainties of the ICs. This will lead to
803 larger uncertainties for the emission inversion. Also the improvement of $PM_{2.5}$
804 forecasts will be limited due to the comparatively poor chemical ICs.

805 This study represents the first step in the simultaneous optimization of chemical
806 ICs and emissions and only surface $PM_{2.5}$ measurements were assimilated. In future
807 work, gas-phase observations of SO_2 , NO_2 and CO will be used to further improve the
808 performance of this DA system.

1103 **List of Figures and Table**

1104 Figure 1. Locations of 77 PM_{2.5} assimilation observation stations (black dot) and the
1105 77 independent observation stations (red triangle) in the model domain. The three
1106 colored boxes mark sub-regions with relatively dense coverage for the Beijing–
1107 Tianjin–Hebei region (JJJ, 12 assimilation stations and 12 independent stations, red
1108 box), the Yangtze River delta (YRD, 24 assimilation stations and 24 independent
1109 stations, blue box) and the Pearl River delta (PRD, 9 assimilation stations and 9
1110 independent stations, green box).

1111
1112 Figure 2. (a) Framework of \mathbf{M}_{SF} and (b) flow chart of the data assimilation system
1113 that simultaneously optimizes the chemical initial conditions and emissions.

1114
1115 Figure 3. Time series of prior ensemble mean RMSE and total spread for PM_{2.5}
1116 concentrations aggregated over all observations over the three sub-regions: (a)
1117 Beijing–Tianjin–Hebei region; (b) Yangtze River delta; (c) Pearl River delta; and (d)
1118 time series of the area mean ensemble spread for $\lambda_{PM2.5}$ over the three sub-regions.

1119
1120 Table 1. Comparison of the surface PM_{2.5} mass concentrations from the control and
1121 assimilation experiments to observations over all analysis times from 6 to 16 October
1122 2014.

1123
1124 Figure 4. Spatial distribution of the PM_{2.5} mass ($\mu\text{g m}^{-3}$) of the (a) observations; (b)
1125 simulation of the control run; (c) analysis of expJ; (d) analysis of expC; (e) increments
1126 of expJ; (f) increments of expC at the lowest model level averaged over all hours from
1127 6 to 16 October 2014.

1128
1129 Figure 5. Hourly area-averaged time series of emission scaling factors (black)
1130 extracted from the ensemble mean of the analyzed $\lambda_{PM2.5}^a$ and the corresponding
1131 analyzed unspeciatiated primary PM_{2.5} emissions $E_{PM2.5}^a$ (blue) over the three
1132 sub-regions: (a) Beijing–Tianjin–Hebei region; (b) Yangtze River delta; and (c) Pearl
1133 River delta.

1134
1135 Figure 6. Hourly area-averaged time series of emission scaling factors extracted from
1136 the ensemble mean of the analyzed (a) λ_{NO}^a ; (b) λ_{SO2}^a ; (c) λ_{NH3}^a over the three
1137 sub-regions: Beijing–Tianjin–Hebei region (JJJ, black), Yangtze River delta (YRD,
1138 green), and Pearl River delta (PRD, blue).

1139
1140 Figure 7. Spatial distribution of $\lambda_{PM2.5}$ at the lowest model level averaged over all
1141 hours from 6 to 16 October 2014.

1142
1143 Figure 8. Spatial distribution of (a) the prior unspeciatiated primary sources of PM_{2.5}
1144 ($\mu\text{g m}^{-2} \text{s}^{-1}$) and (b) the time-averaged differences between the ensemble mean
1145 analysis and the prior values ($\mu\text{g} \cdot \text{m}^{-2} \text{s}^{-1}$) at the lowest model level averaged over all
1146 hours from 6 to 16 October 2014.

1147

1148 Figure 9. Time series of the hourly $PM_{2.5}$ obtained from observations (circle), analysis
1149 (blue line), control run (black line) and hourly output of 48-h forecast in three
1150 megacities: (a) Beijing; (c) Shanghai; and (e) Guangzhou in expJ and (b) Beijing; (d)
1151 Shanghai; and (f) Guangzhou in expC. See text in section 5.4.

1152

1153 Figure 10. Bias of surface $PM_{2.5}$ as a function of forecast range calculated against all
1154 the independent observations over the three sub-regions shown in figure 1: (a)
1155 Beijing–Tianjin–Hebei region; (c) Yangtze River delta; (e) Pearl River delta and
1156 RMSE over (b) Beijing–Tianjin–Hebei region; (d) Yangtze River delta; (f) Pearl
1157 River delta; (g) Normalized RMSE (assimilation divided by control) for expJ and (h)
1158 Normalized RMSE for expC. The 48-h forecasts were performed at each 0000 UTC
1159 from 6 to 16 October 2014 and the statistics were computed from 6 to 16 October.

Figure 1. Locations of 77 PM_{2.5} assimilation observation stations (black dot) and the 77 independent observation stations (red triangle) in the model domain. The three colored boxes mark sub-regions with relatively dense coverage for the Beijing–Tianjin–Hebei region (JJJ, 12 assimilation stations and 12 independent stations, red box), the Yangtze River delta (YRD, 24 assimilation stations and 24 independent stations, blue box) and the Pearl River delta (PRD, 9 assimilation stations and 9 independent stations, green box).
