Supporting information summary:

Number of pages: 10

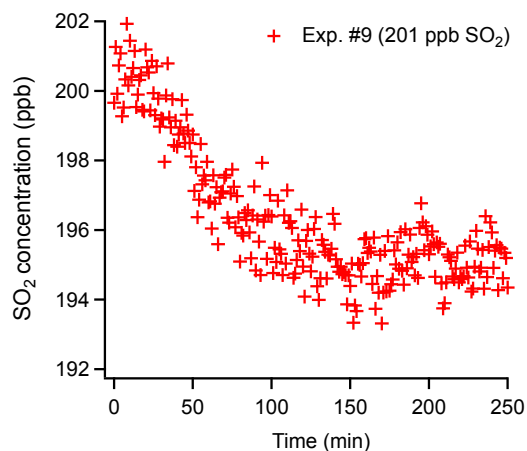

Number of figures: 7

Number of tables: 3

Number of schemes: 2

S1. SO₂ consumption in the presence of HCOOH under dry or humid conditions

B. No formic acid under dry condition

A. With formic acid under dry condition

C. With formic acid under humid condition

Figure S1 SO₂ consumption over the course of the experiments for Exp. #9 (panel A, no formic acid under dry condition), Exp. #18 (panel B, with formic acid under dry condition) and Exp. #19 (panel C, with formic acid under humid condition). By adding formic acid into SOA reaction, less SO₂ consumption was observed (Exp. #18 vs Exp. #9). However, as under more humid conditions, significant SO₂ depletion was detected even with sufficient addition of excess formic acid as Criegee Intermediate scavenger (Exp. #19 vs Exp. #9).

S2. Interactions between SO₂ and peroxides

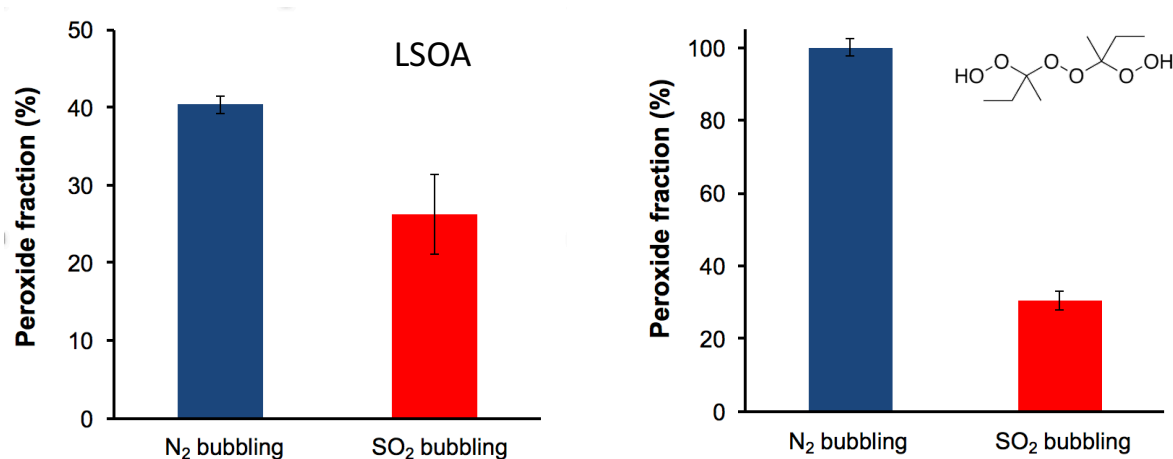

Figure S2 Peroxide fractions in SOA solution bubbled with N₂ and SO₂. Lower peroxide fraction was detected when bubbling SO₂ into LSOA solution (left panel). Significant decrease in peroxide content was also observed when bubbling SO₂ into 2-butanone peroxide solution (right panel), highlighting the importance of organic peroxide in SO₂ oxidation.

S3. SO₂ reaction with other oxidants and SO₃ experiment

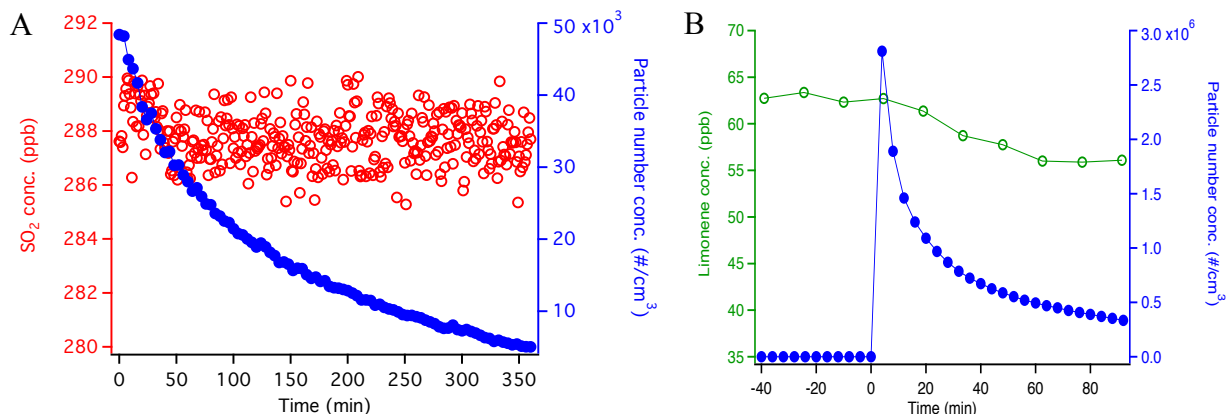

Figure S3 Two sets of control experiments to investigate other potential oxidants of SO₂. Panel A shows the change in SO₂ and particle (ammonium sulfate) concentration as a function of time in the presence of ozone (485 ppb) and formic acid (13 ppm). Panel B shows the change in limonene and particle (sulfuric acid) concentration as a function of time. It is noted that in both figures, particle concentration was not corrected for chamber wall loss.

S4. Identification of organosulfates

Figure S4 Organosulfates observed using ESI-IMS-TOF

Table S1 Identification of sulfur-containing ions based on IMS drift time and Kendrick mass defect

1) SO₂ : Limonene = 100 ppb : 500 ppb

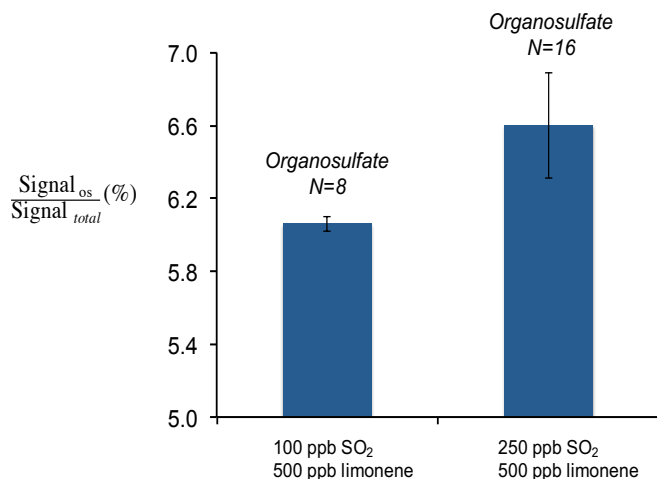

Figure S5 Fraction of total organosulfates as a function of SO₂ injection concentration during SOA formation. Both the amount and the types of organosulfates increase with increasing SO₂ concentration.

S5. α -Pinene SOA formation in the absence or presence of SO_2

Figure S6 Difference in normalized mass spectra between ApSOA in the presence and absence of SO_2 (top panel). Signal of HSO_4^- (m/z 96.96) was not included in this comparison to investigate changes in the organic mass spectra only. Bottom panel shows the average carbon oxidation state of each peak detected in IMS-TOF and the overall average oxidation states of ApSOA (black dashed line) and ApSOA + SO_2 (blue dashed line).

S6. Gas-phase kinetic model for SO₂ oxidation

Scheme S1 Gas-phase reactions for SO₂ oxidation by sCl and peroxides.

Shown in Scheme S1, Criegee intermediates (sCl) and peroxides are formed from limonene ozonolysis and then react with SO₂.

For sCIs:

It is noted that different sCl conformers can be formed in the reaction (Scheme S2). And those conformers may have different reactivities towards reactants including water and water dimer. However, the information is lacking in the literature regarding the reactivity of limonene sCIs. To elucidate the relative importance of different pathways (sCl vs. peroxide) on SO₂ oxidation in our box model, reaction rate constants for sCl reactions in Scheme 1 were estimated and shown in Table S2. Two different values of $k_{\text{sCl}+\text{SO}_2}$ were used in the simulation to examine the sensitivity of different sCl + SO₂ reaction rates on SO₂ oxidation.

Scheme S2 Different conformers of sCIs formed from limonene ozonolysis

Table S2 Rate constants for reactions in Scheme S1

	Rate constant	Value	Note	Literature
k_1	k_{lim+O_3}	$2.1 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$		(Atkinson & Arey, 2003)
k_2	k_{sCI+H_2O} (mono-substituted)	$8.8 \times 10^{-5} k_{sCI+SO_2}$	Estimated from k_{sCI+H_2O} of trans-2-butene	(Berndt et al., 2014)
	k_{sCI+H_2O} (di-substituted)	$4.0 \times 10^{-6} k_{sCI+SO_2}$	Estimated from k_{sCI+H_2O} of tetramethylethylene	(Berndt et al., 2014)
k_3	$k_{sCI+(H_2O)_2}$	$1 \times 10^3 k_{sCI+H_2O}$		(Huang, Chao, & Lin, 2015)
k_4	$k_{sCI+formic\ acid}$	$3 \times k_{sCI+SO_2}$		(Sipilä et al., 2014)
k_5	$k_{decompose}$ (mono-substituted)	$1.2 \times 10^{12} k_{sCI+SO_2}$ molecule cm^{-3}	Estimated from $k_{decompose}$ of trans-2-butene	(Berndt et al., 2014)
	$k_{decompose}$ (di-substituted)	$4.2 \times 10^{12} k_{sCI+SO_2}$ molecule cm^{-3}	Estimated from $k_{decompose}$ of tetramethylethylene	(Berndt et al., 2014)
k_{sCI}	k_{sCI+SO_2} (high)	$3.9 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$	Estimated from k_{sCI+SO_2} of CH ₂ OO	(Welz et al., 2012)
	k_{sCI+SO_2} (low)	$8 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$	Estimated by Mauldin et al. based on field observations	(Mauldin III et al., 2012)

For peroxides:

A simplified bimolecular reaction was assumed in this study. The reaction is modelled as an irreversible pathway to match the observed SO₂ decay in our experiments. The simplified model is used to qualitatively demonstrate the importance of peroxide reaction pathway under our experimental conditions. It should be noted that more information about the reaction mechanisms, such as the Henry's Law constants of organic peroxides, is needed to accurately model this reaction.

The reaction rate between SO₂ and peroxide can be calculated as:

$$R_{SO_2+peroxide} = k_{OOH}[peroxide] [SO_2]$$

where k_{OOH} is the pseudo reaction rate constant (in $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$); $[peroxide]$ and $[SO_2]$ are the concentrations of peroxide and SO₂ (in molecule cm^{-3}), respectively.

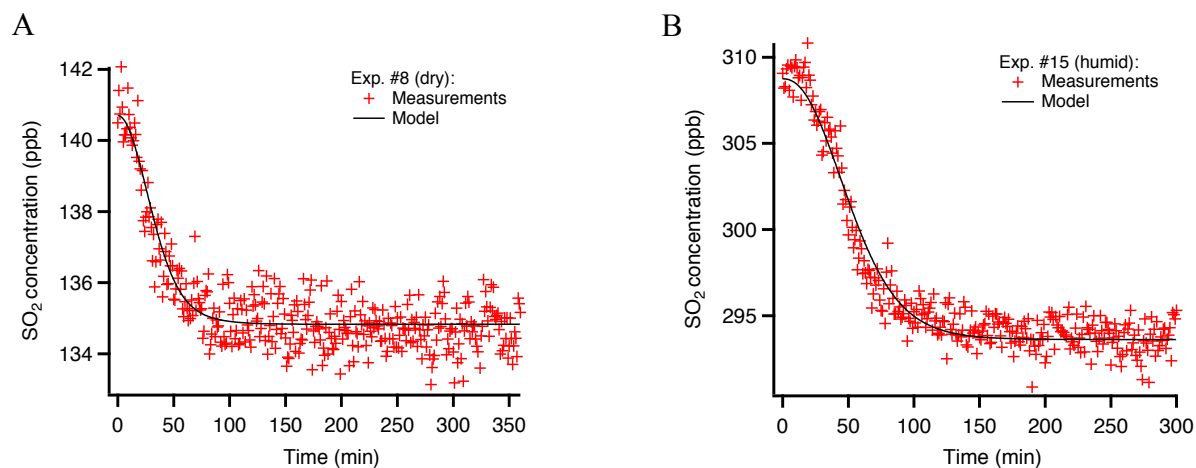

Figure S7 Examples of measured and model-simulated SO₂ concentrations under dry (A) and humid conditions (B).

Shown in Fig. 7S, the time trends of SO₂ in the model simulation (Scheme S1) matches those over the course of the experiments under both dry and humid conditions. Constrained from our laboratory observations, sCI yield from limonene ozonolysis (y_{sCI}) was calculated to be 0.32, which is consistent with the results from Sipilä et al. (0.27 ± 0.12) (2014). $y_{peroxide}$ that represents the available amount of peroxides in the aqueous phase that can react with SO₂, was calculated to be 0.06 and 0.43 under dry (10% RH) and humid (50% RH) conditions, respectively. This is likely because that under humid conditions, more aerosol water is available for peroxides to partition and to react with SO₂. It was also observed that k_{sCI+SO_2} did not play an important role in SO₂ oxidation in this simulation. Little change was observed when different reaction rates (k_{sCI+SO_2}) in Table S2 were used, indicating that the consumption of SO₂ was limited by the concentrations of sCIs that were available for SO₂ reaction.

S7. SO₂ uptake coefficient by reacting with peroxides

The uptake coefficient of SO₂ (γ) to the particles can be estimated using the following equation (Seinfeld & Pandis, 2006):

$$\frac{d[SO_2]}{dt} = -\frac{1}{4}\gamma A\tilde{v}[SO_2] \quad (1)$$

, where $[SO_2]$ is SO₂ concentration in the gas phase (molecules cm⁻³); A is the total surface concentration of particles (m² m⁻³) derived from particle size distribution measured by SMPS; \tilde{v} is the mean molecular speed of SO₂ (m s⁻¹) which is obtained from:

$$\tilde{v} = \sqrt{\frac{8RT}{MW\pi}} \quad (2)$$

, where R is the gas constant; T is the experiment temperature; MW is the molecular weight of SO₂.

To calculate the uptake coefficient, we assume the fraction of SO₂ that reacted with peroxides ($f_{(SO_2+peroxide)}$) was constant over the course of the experiment, Eq. (1) can be then modified as:

$$\ln \frac{[SO_2]_0}{[SO_2]_t} = \ln \frac{[SO_2]_0}{[SO_2]_0 - ([SO_2]_0 - [SO_2]_t) f_{(SO_2+peroxide)}} = \frac{1}{4} \gamma A \tilde{v} \Delta t \quad (3)$$

where $[SO_2]_0$ and $[SO_2]_t$ are SO₂ concentration at 0 min and t min, respectively; Since SO₂ consumption ceased when t is around 150 min for all the limonene experiments under humid conditions, $\Delta t = 150$ min was used in all the calculations. We therefore present a conservative estimate of SO₂ uptake coefficients, shown in Table S3.

Table S3 Estimated uptake coefficients of SO₂ through reacting with peroxides from limonene ozonolysis under humid conditions

Exp. #	$[SO_2]_{0 \text{ min}}$ (ppb)	$[SO_2]_{150 \text{ min}}$ (ppb)	S (m ² m ⁻³) ^a	$f_{(SO_2+peroxide)}$ ^b	RH (%)	γ
14	144.3	128.9	2.24×10^{-3}	0.84	55%	5.1×10^{-5}
15	308.8	293.8	2.32×10^{-3}	0.76	47%	1.8×10^{-5}
19	262.2	252.2	1.73×10^{-3}	0.77	50%	1.9×10^{-5}
20	605.4	593.0	1.57×10^{-3}	0.75	52%	1.1×10^{-5}

^a: average total particle surface area concentration in the first 150 min of the experiments;

^b: the fraction of SO₂ that reacted with peroxides, calculated using the modeling simulation results from Section S6
