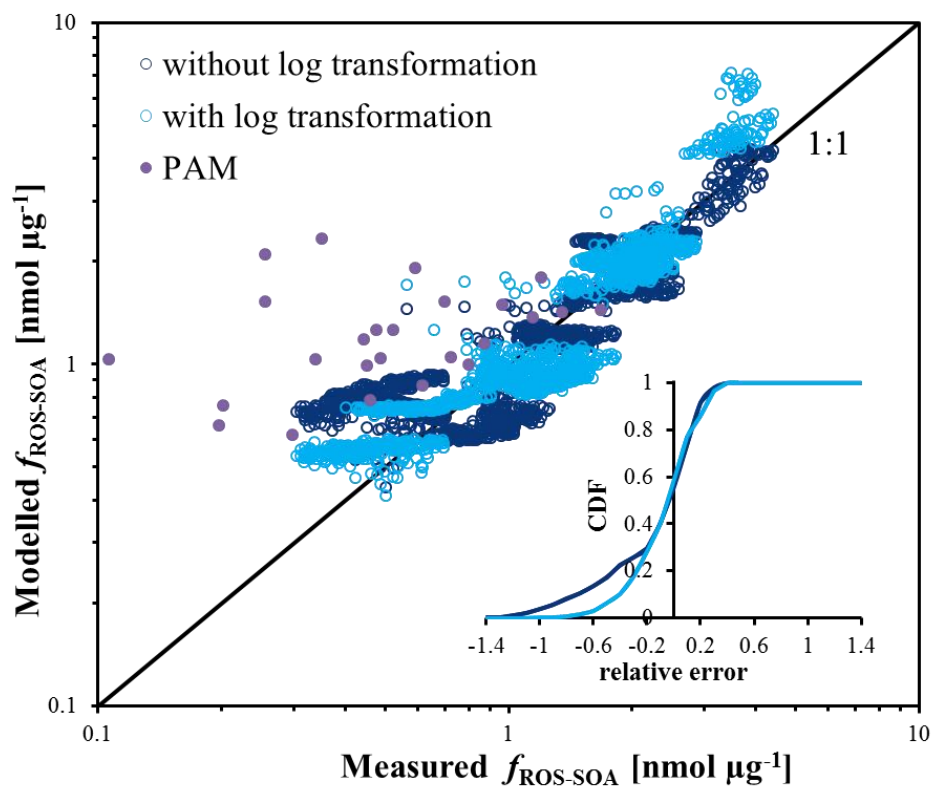

Figure S3: Variation of the fraction of ROS in SOA, $f_{ROS-SOA}$, with the fraction of $m/z44$ in the secondary organic aerosol measured by the AMS (f_{44-SOA} , x-axis) and the OH exposure estimated from the decay of d9-butanol measured by the PTR-ToF-MS (color code). Data are collected from two different smog chambers (SC) and from the PAM chamber. Dashed lines are isopleths of constant OH exposures, while solid lines are obtained by isolating the effect of OH exposure from the other variables. Numbers 1-5 represent the sequence of the five 7- m^3 SC experiments, Number 6 represents a single 27- m^3 SC experiment.

5 **Figure S4:** Comparison of the performance of two multiple regression models, with and without log-transformation of the data. The $f_{\text{ROS-SOA}}$ measured in the PAM is predicted using the same parameterization and results are displayed for comparison. The inset shows the cumulative density function (CDF) of the relative model residuals (measurements-model).
