

S1 Statistical analysis of simulated warm season MDA8 O₃ and annual mean PM_{2.5} compared to measurements

Table S1: Warm season (April-September) mean of daily maximum 8-hour running mean O₃ concentrations (MDA8 O₃) and annual mean PM_{2.5} concentrations at the global and regional resolutions compared to observations from 52 and 25 stations within the EMEP network, respectively.

Season		Obs.	140 km	50 km
MDA8 O₃ (Apr - Sept)	Mean ($\mu\text{g m}^{-3}$)	86.3	95.6	94.8
	NMB (%)		10.9	8.9
	SD ($\mu\text{g m}^{-3}$)	9.2	14.7	14.2
	Difference (%)			1
PM_{2.5} (Annual)	Mean ($\mu\text{g m}^{-3}$)	11.4	12.6	13.7
	NMB (%)		10.5	20.2
	SD ($\mu\text{g m}^{-3}$)	5.1	2.8	5.0
	Difference (%)			-9

S2 Seasonal and country level evaluation for O₃

We further analyse how the seasonality in O₃ concentrations simulated at the two resolutions varies seasonally and also geographically at the country level (Fig. S1). During winter, O₃ concentrations at southerly locations in Greece and Italy (Fig. S1 red box) show the largest differences between the two resolutions, with an overestimate of $\sim 50 \mu\text{g m}^{-3}$ at the global resolution compared to EMEP measurements. In contrast to the majority of the sites during winter, simulated O₃ concentrations at the regional resolution are higher compared to the global resolution for several locations in Austria, Hungary and Slovakia (red circle). Similar to winter, O₃ concentrations at the same locations in Italy are also largely overestimated by both model resolutions in summer ($\sim 50 \mu\text{g m}^{-3}$, Fig. S1c). In autumn, the largest overestimates of low O₃ concentrations at the regional resolution occur at northern European locations in the Netherlands and Belgium, (Fig. S1d - red box).

In spring, summer and autumn, O₃ concentrations simulated at both resolutions in Malta are much higher compared to measurements ($\sim 40 \mu\text{g m}^{-3}$; Fig. S1b, c and d -red circle). This is due to the fact that at both resolutions, the grid box covering the Maltese Islands is represented as ocean and not land. Deposition of O₃ is typically less over the sea than compared to over land, potentially leading to an overestimation in simulated O₃ concentration compared to measurements at this location.

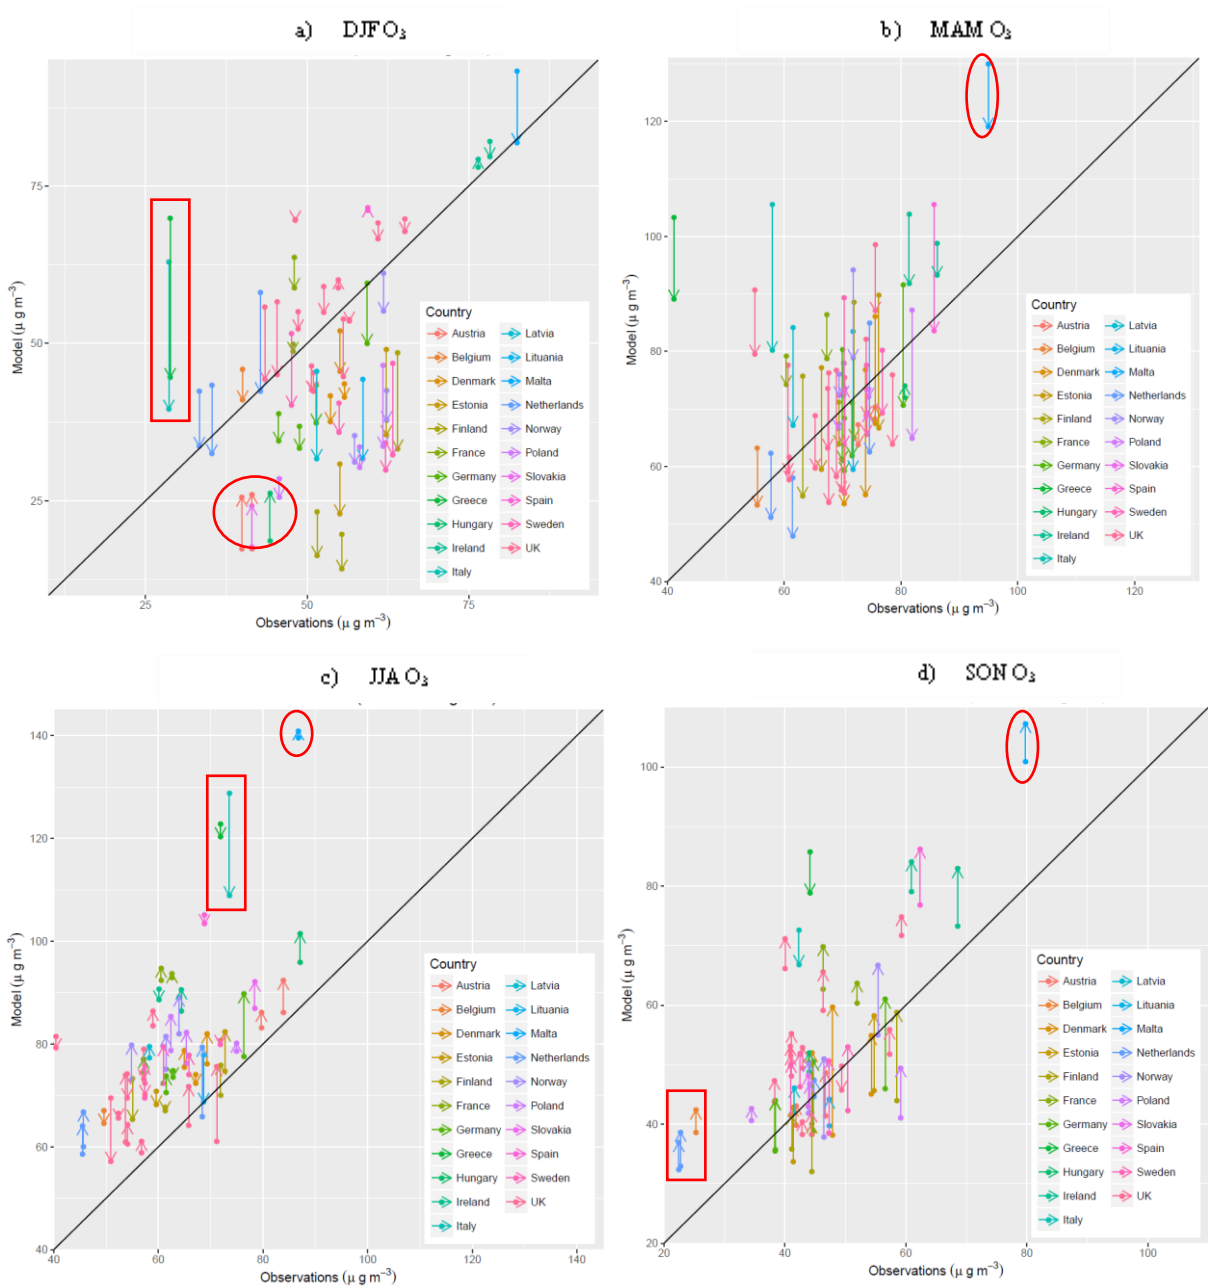

Figure S1: Modelled versus observed seasonal mean O_3 for a) DJF b) MAM c) JJA d) SON 2007 over a subset of 52 sites across the EMEP network as shown in Fig. 1. The arrow tails mark O_3 concentrations at the global resolution while the arrow heads represent the corresponding O_3 concentrations at the regional resolution.

S3 Additional figures on the impact of model resolution on pollutant concentrations

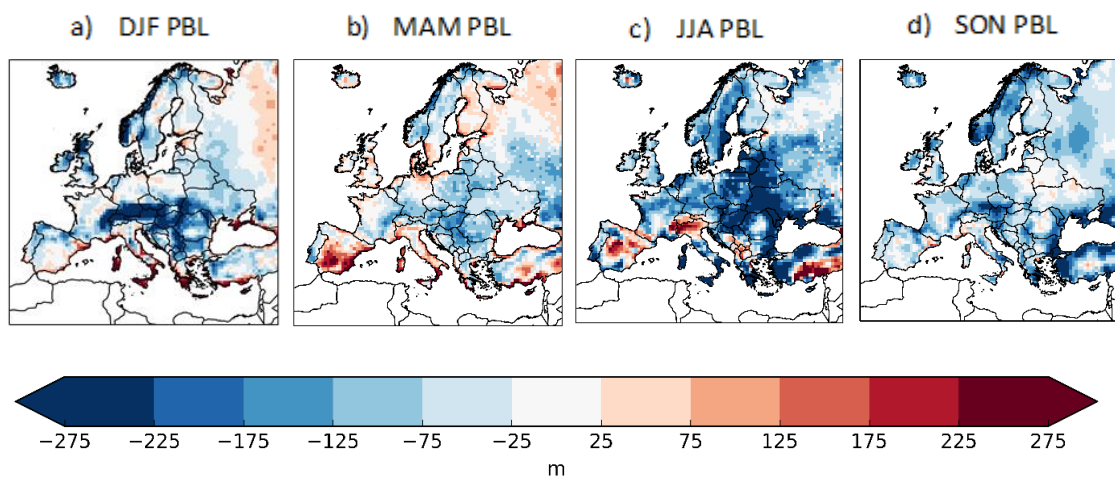

Figure S2: Difference between global and regional seasonal mean boundary layer height (PBL global resolution – PBL regional resolution) for a) DJF b) MAM c) JJA and d) SON for 2007

Figure S3 Seasonal mean modelled vs observed PM_{2.5} for 25 sites across the EMEP network for the year 2007. The arrow tails mark PM_{2.5} concentrations at the global resolution while the arrow heads represent the corresponding PM_{2.5} concentrations at the regional resolution. The 1:1 line shows agreement between observed and simulated PM_{2.5}.

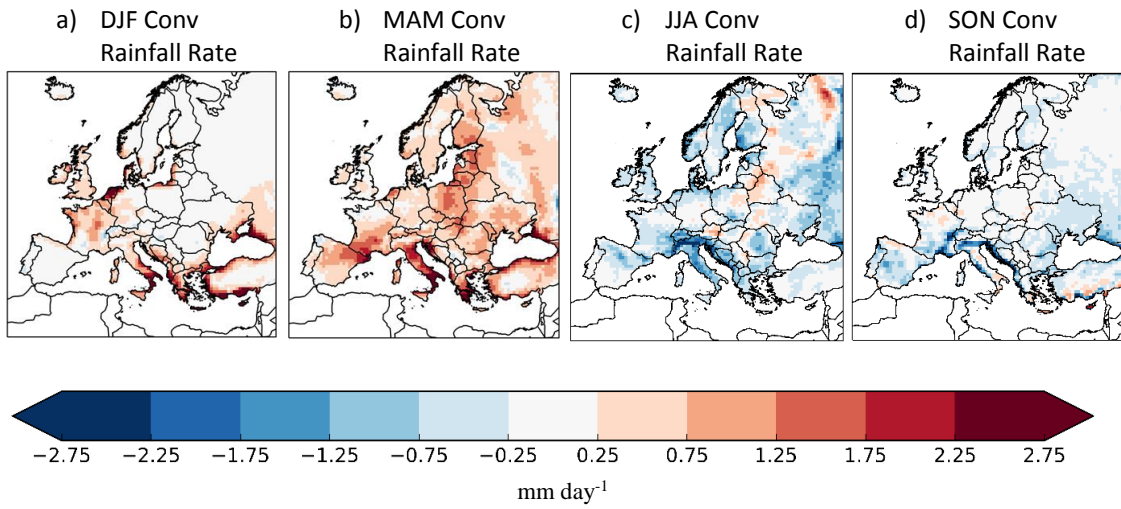

Figure S4: Difference between global and regional seasonal mean convective rainfall rate (mm day^{-1}) for a) DJF b) MAM c) JJA and d) SON for 2007

S4 Additional figures on the effect of applying population-weighting to pollutant concentrations

Figure S5: a) Difference between MDA8 O₃ concentrations with and without population-weighting as simulated by the global (orange bars) and regional (blue bars) resolutions b) same holds for annual mean PM_{2.5} concentrations.
