7 **Abstract.** In 1926 the stratospheric ozone measurements of the Light Climatic Observatory (LKO) of Arosa  
8 (Switzerland) started, marking the start of the world's longest total (or column) ozone measurements. These  
9 measurements were driven by the recognition of the importance of atmospheric ozone for human health as well  
10 as by scientific curiosity in this by then not well characterized atmospheric trace gas. Since the mid-1970s  
11 ground-based measurements of stratospheric ozone have also been justified to society by the need to document  
12 the effects of anthropogenic Ozone Depleting Substances (ODSs), which cause stratospheric ozone depletion.  
13 Levels of ODSs peaked around the mid-1990s as a result of a global environmental policy to protect the ozone  
14 layer implemented by the 1987 Montreal Protocol and its subsequent amendments and adjustments.  
15 Consequently, chemical ozone depletion caused by ODSs stopped worsening around the mid-1990s. This renders  
16 justification for continued ozone measurements more difficult, and is likely to do so even more in future, when  
17 stratospheric ozone recovery is expected. Tendencies of increased cost savings in ozone measurements seem  
18 perceptible worldwide, also in Arosa. However, the large natural variability in ozone on diurnal, seasonal and  
19 interannual scales complicates to demonstrate the success of the Montreal Protocol. Moreover, chemistry-climate  
20 models predict a "super-recovery" of the ozone layer in the second half of this century, i.e. an increase of ozone  
21 concentrations beyond pre-1970 levels, as a consequence of ongoing climate change. This paper presents the  
22 evolution of the ozone layer and the history of international ozone research and discusses the justification of  
23 these measurements for past, present and future.

24

## 25 **1. Introduction**

26

27 The world's longest time series of total (or column) ozone observations is from Arosa in the Swiss Alps, made at  
28 the "Light Climatic Observatory" (Lichtklimatisches Observatorium, LKO). The long total ozone dataset is  
29 valuable for long-term trend analyses of stratospheric ozone. In addition, other important ozone measurements,  
30 such as Umkehr and surface ozone measurements are being performed in Arosa. Since the 1970s, when  
31 anthropogenic stratospheric ozone depletion became a subject of public concern, the measurements at LKO  
32 became more and more important (Staehelin et al., 2016). A comprehensive report on the history of the LKO is  
33 presently in preparation (Staehelin and Viatte, in prep.). Here we focus on the justification to society for these  
34 measurements throughout the long history of the LKO in connection to the development of international  
35 stratospheric ozone research. This paper is based on the extensive correspondence by F. W. Paul Götz - ozone  
36 pioneer and founder of the LKO - which is treasured in the LKO archives located in Payerne, Switzerland, on the  
37 annual reports of the "Kur- und Verkehrsverein Arosa" (KVV Arosa, "Health Resort Authority of Arosa", see

38 below), and on other research. Staehelin and Viatte (in prep.) divided the history of LKO into five distinct  
39 periods (see Sections 2-6 below). Section 7 includes some remarks on the future of measurements at the LKO,  
40 and a summary and conclusions are presented in Section 8.

## 41 **2. Period 1921-1953: Friedrich Wilhelm Paul Götz**

42

### 43 **2.1. Therapy for tuberculosis prior to the availability of antibiotics**

44

45 The first ozone measurements at Arosa were a part of medical research focused on the treatment of tuberculosis  
46 (TB). Before modern antibiotics became available (a few years after World War II), TB was a serious sickness  
47 with high mortality. The best available therapy for lung TB at the time was believed to be the “rest cure therapy”  
48 (as proposed, e.g. by Karl Turban, one of the leading medical doctor in Davos, see e.g. Virchow, 2004). At the  
49 end of the 19<sup>th</sup> century and the beginning of the 20<sup>th</sup> century, many sanatoria and hotels were constructed in  
50 Alpine villages such as Davos and Arosa. During “rest cure therapy”, which was fully developed in the first  
51 decades of the 20<sup>th</sup> century, the patients stayed outside on balconies during the day under strict hygienic  
52 conditions, usually for several months at a time. Recovery mainly occurred simply by resting. From a modern  
53 medical perspective, such rest under strict hygienic control (in order to prevent reinfection) in special lung  
54 clinics was probably the most helpful type of therapy before treatment by antibiotics became possible.

55 In 1905, Turban proposed opening an institute for scientific study of the “rest cure therapy” of lung TB (SFI,  
56 1997). However, because of a lack of consensus among medical doctors, such an institute was founded only in  
57 1922. On 26 March 1922, the municipality of Davos (“Landsgemeinde”) decided to create a foundation for an  
58 institute for high mountain physiology and tuberculosis research (“Institut für Hochgebirgsphysiologie und  
59 Tuberkuloseforschung”, today the “Schweizerisches Forschungsinstitut für Hochgebirgsklima und Medizin, SFI”  
60 in Davos). The resources for operating the institute mainly originated from a small fee that was paid by all guests  
61 of the town, who needed register when staying in Davos (a form of “tourist tax”).

62 The medical doctors of Davos and Arosa were convinced that the high altitude climate was an important factor  
63 for optimal recovery from lung TB and in order to study this further, the potentially relevant environmental  
64 factors needed to be investigated. At this point, Carl Dorno played an important role. He was a rich industrialist  
65 from Königsberg (Germany), who came to Davos because his daughter suffered from lung TB. She  
66 unfortunately passed away a few years after arriving in Davos, but Dorno remained and founded an institute to  
67 study the environmental factors important for treating TB using his own funds in 1907 (SFI, 1997). During the  
68 first World War and in the subsequent period of inflation, Dorno lost most of his financial resources. On 18  
69 February 1923, the municipality of Davos decided to support the “Prof. Dorno Institute”, the nucleus of the  
70 world famous Physical Meteorological Observatory Davos (PMOD), which serves since 1971 also as World  
71 Radiation Center (WRC) of the World Meteorological Organization (WMO). When Dorno retired as director in  
72 1926, the institute was integrated as an independent department into the institute for high mountain physiology  
73 and tuberculosis research in Davos and was financed by the Davos community, similar to the other institutes.  
74 Despite several studies, it was not possible to demonstrate the superiority of the Alpine climate for recovery  
75 from (lung) TB (Schürer, 2017).

76

77 **2.2. F.W.P. Götz and the foundation of the LKO (LKS)**

78

79 Friedrich Wilhelm Paul Götz grew up in Southern Germany (Göppingen, close to Stuttgart) and went to Davos  
80 for the first time prior to the beginning of the First World War to recover from lung TB, when he was working  
81 on his PhD thesis in astronomy (see Fig. 1). He stayed twice in the “Deutsche Heilstätte” sanatorium (1914-  
82 1915) and he was then released as “fit for work”. For the following years (1916-1919) he intermittently taught at  
83 the “Fridericianum” German school in Davos and later worked with Dorno for an unknown duration (1919-  
84 1920). See Staehelin and Viatte for more details (in prep.).

85

**Friedrich Wilhelm Paul Götz**

1891	Born on 20 May in Heilbronn (Germany)
1891-1910	Childhood in Göppingen (near Stuttgart, Germany)
1910	Start of Studies in mathematics, physics and astronomy in Heilbronn (Germany)
1914-1915	Davos: recovery from tuberculosis at «Deutsche Heilstätte»
1916-1919	Intermittently high school teacher at the «Fridericianum» (German School) in Davos, Switzerland
1919	Dissertation, University of Heidelberg (Germany), thesis on the photometry of the moon surface
1919-1920	Part-time coworker of Dorno in Davos
1921	Habilitation and lecturer at the University of Zürich, Switzerland
1932	Marries Margarete Karoline Beverstorff (27. Dec.)
1940	Promotion to «Titular-Professor» at University of Zürich, responsible for teaching courses in meteorology
1950-1954	Physical and mental illness (arteriosclerosis)
1954	Died on 29 Aug. in Chur (Switzerland)

86

87 **Figure 1.** Biography of F.W. Paul Götz, founder of the Light Climatic Observatory in Arosa.

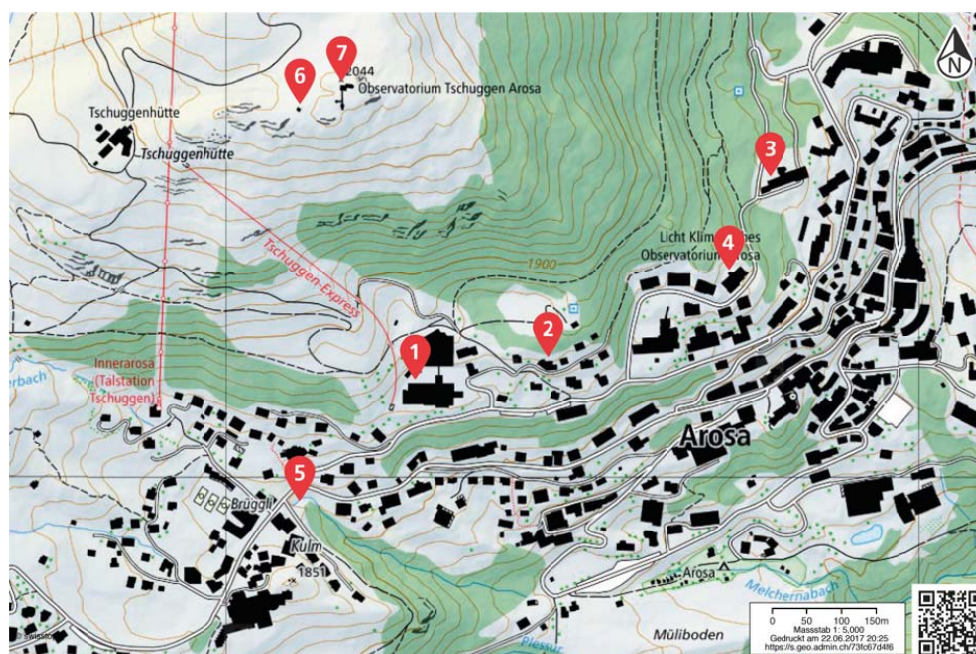

88

89 It appears that Götz was the main driver behind the initiative to make atmospheric measurements at Arosa. He  
90 likely first contacted the Arosa medical doctors and together they subsequently made a request to the managing  
91 committee of the KVV Arosa in March 1921 to hire Götz in order to make climate studies relevant for health.  
92 The KVV Arosa (Kur- und Verkehrsverein Arosa, “Health Resort Authority of Arosa”) was an organization that  
93 had a fairly large budget, mainly supported through the “tourist” tax (i.e. a fee to be paid by foreigners/guests  
94 staying in Arosa), which was also used to cover the costs of various other activities that currently fall under the  
95 responsibility of the municipality. This request was supported by the General Assembly of the KVV Arosa that  
96 took place on 20 August 1921 and Götz was asked to found the “Light Climatic Station” (LKS), which later  
97 became known as the “Light Climatic Observatory (LKO)”. The measurements taken at the LKS were to  
98 complement the meteorological observations made at Arosa since 1884 by the Swiss national weather service  
99 (now “MeteoSwiss”). These atmospheric measurements were thought to be relevant for studying recovery from  
100 TB. Arosa was the first municipality to finance an institute with the task of studying environmental factors  
101 favorable to curing (lung) TB. The support Götz obtained from the KVV Arosa was rather modest and later he

102 secured additional regular funding from both the Chur-Arosa railway company and the Arosa municipality (for  
103 more detail see Staehelin and Viatte, in prep.). The LKS measurements were made on the roof of the Inner-Arosa  
104 Sanatorium, where the “Grand Hotel Tschuggen” is located at present (see Fig. 2).

105

106

107 **Figure 2.** Map of important locations relevant to the Arosa Light Climatic Observatory (LKO). LKO  
108 measurement sites: 1) Sanatorium Inner-Arosa; 2) Villa Firnelicht; 3) Florentinum; 4) Haus zum Steinbruch.  
109 Other sites: 5) Götzbrunnen (fountain in honor of Götz); 6) Hut where Götz made his nighttime measurements in  
110 Tschuggen; 7) Astrophysical observatory at Tschuggen. With permission of swisstopo (Swiss digital maps,  
111 [geo.admin.ch](http://geo.admin.ch)).

112  
113

114 For the first few years Götz was able to borrow an instrument from Dorno (who was based in Davos, see 2.1) to  
115 measure “biologically active ultraviolet (UV) radiation”. This instrument had been adapted and used by Dorno  
116 and consisted of a photoelectric cell with a cadmium (Cd) cathode (Levy, 1932). Götz published several papers  
117 using measurements covering the period November 1921-May 1923 (Götz 1925, 1926a and b). He found the  
118 first indication of the seasonal variability of stratospheric ozone in the northern mid-latitudes, with a minimum in  
119 autumn and maximum in spring, a very important result, which would later help to understand the global issue of  
120 stratospheric circulation. This result was in fact published earlier than the well-known publication of Dobson and  
121 Harrison (1926). Dorno did not agree with Götz’s Cd-cell results, and this led to an open dispute published in the  
122 literature (Dorno, 1927). It seems likely that there were also some personal difficulties between Dorno, who was  
123 26 years older, and Götz, which became more evident with time. It also appears there were issues between the  
124 medical doctors from Davos and Arosa, with the latter suggesting that the scientific studies made in Arosa  
125 should be coordinated with those from Davos. They also asked that the institute for high mountain physiology

126 and tuberculosis research in Davos (Institut für Hochgebirgsphysiologie und Tuberkuloseforschung in Davos) be  
127 renamed to include Arosa, but it seems that these efforts failed since members of the Davos community wanted a  
128 higher financial contribution from Arosa to the institute (based on the principle of equal duties, equal rights  
129 (“gleiche Rechte, gleiche Pflichten”). The KVV Arosa was, however, not willing to pay the requested amount.

130

### 131 **2.3. LKO under Götz**

132

133 1926 was an important year for Götz. After the debate regarding cooperation between the Arosa and Davos  
134 medical doctors took place (for more details see Staehelin and Viatte, 2018) Götz moved into the “Villa  
135 Firnelicht” (see Fig. 3), which is very close to the Inner-Arosa Sanatorium, where measurements had previously  
136 been performed (see Fig. 2). Evidence suggests that Götz used family resources to build the large house,  
137 probably the inheritance from his father, Paul Götz, who owned a ironmongery (“Eisenwarenhandlung”) in  
138 Göppingen (Trenkel, 1954) and died in 1926. “Villa Firnelicht” offered space for atmospheric observations on  
139 the roof and a balcony. It hosted three apartments and was therefore too large for just Götz and his wife. When  
140 Götz moved into “Villa Firnelicht” the institute was renamed to “Light Climatic Observatory” (Lichtklimatisches  
141 Obervatorium (LKO)). Götz invited colleagues to come to the LKO for sabbatical-type collaborations and to  
142 make atmospheric observations.

143 After the first conjectures that the amount of biologically active UV-radiation was determined by stratospheric  
144 ozone levels, Götz devoted a large part of his time to stratospheric ozone research. He realized that studying  
145 stratospheric ozone required suitable instrumentation and using resources from the KVV Arosa he mandated the  
146 Schmidt-Haensch company based in Berlin (Germany) to construct a Buisson-Fabry type of a sun  
147 spectrophotometer, with a design supervised by him. The instrument was delivered and used by Götz in  
148 his expedition in Spitzbergen (see below), but it is not known to us why it subsequently was only very rarely  
149 used. In 1926 Götz started a very fruitful collaboration with Gordon Dobson, a British physicist and  
150 meteorologist at the University of Oxford, who had just developed his first spectrophotometer (Walshaw, 1989).  
151 Götz began continuous total ozone measurements at Arosa using an instrument called a Fery spectrograph,  
152 which was developed by Dobson (Staehelin et al., 1998a). Later, Götz used improved sun spectrophotometers  
153 also constructed by Dobson (abbreviated as Dx, where x is the fabrication number; see Fig. 4). Dobson was very  
154 interested in the favorable climate and good weather and working conditions at the LKO. Thus, he arranged that  
155 the instruments were formally made available to the LKO through the International Association of Meteorology  
156 and Atmospheric Sciences (IAMAS, an association of the International Union of Geodesy and Geophysics  
157 (IUGG)). This allowed Götz to make total ozone observations at Arosa for many years, while it would have been  
158 very difficult for him to buy such spectrophotometers. After 1948 these instruments were formally borrowed  
159 through the International Ozone Commission (IO3C) of the IAMAS. Götz became one of the leading ozone  
160 researchers. He developed the “Umkehr method”, which provided the first reliable information about the vertical  
161 ozone profile. This method is based on the “Umkehr effect”, which Götz discovered during his expedition to  
162 Spitzbergen in 1929 (Götz, 1931). The first series of Umkehr measurements (besides a limited number of  
163 observations made in Oxford in 1931) was performed together with Dobson and his coworker Meetham on the  
164 roof of the “Villa Firnelicht” in 1932/33 (Götz et al., 1934).

165

166

167 **Figure 3.** “Villa Firmelicht”, Götz’s house in which the LKO, Götz’s observatory was hosted (see text).

168

169 Götz was active in the international research community, as a member of the International Radiation  
170 Commission from 1932-1936 (Int. Rad. Com., 2008) and as a member of the IO3C from 1948, when it was  
171 formally established at the Seventh IUGG Assembly, until 1954 (Bojkov, 2012). Götz’s research interests were  
172 broad, concerning many aspects of weather and climate, leading also to the publication of two books focusing to  
173 the statistical analysis of meteorological observations made at Arosa (Götz, 1926b; 1954).

176

**Figure 4.** Sun photometers operated at Arosa from 1921-present (for more details see Staehelin and Viatte in prep.).

177

178

179

During World War II, the KVV Arosa's financial support of the LKO was substantially decreased and Götz considered leaving Switzerland. Karl Wilhelm Franz Linke, professor and director of the Institute for Meteorology and Geophysics of the Goethe University of Frankfurt am Main (Germany) made him two offers to move to Frankfurt. At the same time Heinrich von Ficker, professor at the University of Vienna and director of the Central Institute for Meteorology and Geodynamics, asked Götz to become professor in Vienna (Austria). However, Götz decided to stay in Arosa in the Swiss Alps. If Götz had moved to Frankfurt or Vienna in World War II, the column ozone measurements made at LKO would likely have come to an end after just about one decade of measurements.

186

187

A few years after World War II, when modern antibiotics become available, the reasons for atmospheric studies related to tuberculosis therapy at LKO gradually became obsolete (Schürer, 2017). Moreover, many of the rich clients, who had been important to some of the sanatoria, no longer could afford to travel to Switzerland because of the 1930s economic depression. However, starting in the 1930s, Arosa was progressively promoted as a winter sport resort area. In November 1943, Götz provided a new justification for the measurements at LKO, proposing that the excellent air quality in Arosa was a "natural resource" and that such resort areas should quantify their air quality to obtain an objective grading (Götz, 1954). This proposal was part of a project for the "medical enhancement" of Switzerland's resort areas ("Medizinischer Ausbau der Kurorte"), which was termed "climate action" ("Klimaaktion") and funded by the Swiss Federal Office for Transport (Schweizerisches Bundesamt für Verkehr). Through this project, Götz obtained support to study air pollution by making surface ozone measurements. He was convinced that high ozone concentrations were an indication of healthy alpine air,

197

198 since at the time polluted urban air had low ozone concentrations (caused by the high city-center NO<sub>x</sub>  
199 emissions). After World War II, Götz significantly increased efforts to obtain additional support for research at  
200 LKO by applying for a wide range of grants, which allowed him to hire collaborators who assisted him with  
201 measurements and scientific work.

202 Götz suffered from physical as well as mental (arteriosclerosis) health problems in the last years of his life  
203 (Trenkel, 1954) and he died at the age of 63 in 1954. Dr. Gertrud Perl was his main assistant from 1948 onwards,  
204 She continued making measurements even after Götz's death, but on the roof the Florentinum Sanatorium (see  
205 Fig. 2), because of difficulties with Götz's wife, who owned "Villa Firnelicht". Unfortunately, the Dobson  
206 instrument was damaged during transport to the Florentinum, so that there are a few months of data missing from  
207 the Arosa total ozone time series.

### 208 **3. Period 1954-1962: First intermediate period**

209

210 After Götz's death, it was uncertain for several years whether the measurements at LKO would at all continue.  
211 Jean Lugeon, the director of MeteoSwiss (Meteorologische Zentralanstalt at the time), supported the ozone  
212 measurements at Arosa during this critical period. He knew Götz personally, since they had taught together at the  
213 University of Zürich, and he was aware of the scientific value of the measurements. He was also the coordinator  
214 of the Swiss contribution to the International Geophysical Year (IGY) coming up 1958, in which total ozone  
215 measurements of Arosa were recognized as geophysically significant data set. For a few years, the Swiss  
216 National Science Foundation (SNSF) contributed to the salary of Perl in addition to the support received from  
217 the KVV Arosa and the Arosa municipality. From 1957 onwards, the Arosa total ozone measurements were  
218 additionally supported by MeteoSwiss. Hans-Ulrich Dütsch, a former graduate student of Götz (see Sect. 4.1),  
219 also played an important role for the continuation of ozone measurements at Arosa. He wrote a letter to the  
220 councilor of the Swiss Federal government in Bern responsible for the Federal Department of Home Affairs. In  
221 his response, the councilor indicated that MeteoSwiss could be mandated to assume the responsibility for the  
222 Arosa ozone measurements based on several resolutions of the World Meteorological Organization (WMO),  
223 which advised the national meteorological services to undertake ozone measurements. It was suggested that the  
224 Federal Meteorological Commission ("Eidgenössische Meteorologische Kommission"), the committee  
225 responsible for overseeing MeteoSwiss, should consider this in a comprehensive way, also looking at additional  
226 options, such as moving the LKO measurements to nearby Davos. Dütsch disagreed with the move to Davos,  
227 since he feared that this might lead to a serious discontinuity in the ongoing Umkehr measurements, because of  
228 larger aerosol contamination in Davos. In the end, the LKO stayed independent and was not integrated into  
229 MeteoSwiss, but MeteoSwiss and KVV Arosa provided financial support and measurements were continued at  
230 Arosa.

### 231 **4. Period 1962-1985: Hans-Ulrich Dütsch**

232

#### 233 **4.1. Dütsch and international ozone science**

234

235 After Dütsch completed his PhD thesis in 1946 (title: “Photochemische Theorie des atmosphärischen Ozons  
236 unter Berücksichtigung von Nichtgleichgewichtszuständen und Luftbewegungen”, Photochemical theory of  
237 atmospheric ozone under consideration of non-equilibrium states and air movements), he first worked as a  
238 physics teacher at a high school (Gymnasium) in Zürich. However, he remained interested in ozone research and  
239 eventually decided to pursue a career in science (see Fig. 5). From 1962-1965 he lived with his family in Boulder  
240 (Colorado, USA) while working as a researcher at the newly founded National Center for Atmospheric Research  
241 (NCAR). Together with Carl Mateer, Dütsch was the first to use modern computers to retrieve vertical ozone  
242 profiles with the Umkehr method.

243 In 1965 Dütsch was appointed as full professor at the ETH Zürich (ETHZ) where he served as director of the  
244 Laboratory of Atmospheric Physics (LAP, later to merge with the Institute of Climate Sciences to become the  
245 Institute for Atmospheric and Climate Science (IAC)). Dütsch’s research continued to focus on ozone, and thus  
246 he extended Swiss ozone measurements (see Section 4.2).

247

#### Hans-Ulrich Dütsch

1917	Born on 26 Oct. in Winterthur (Switzerland) Childhood in Winterthur
1940	Diploma in theoretical physics with a minor in meteorology, University of Zürich
1943-1946	Graduate student of Getz
1947-1962	High school (Gymnasium) teacher in physics in Zurich, continuing ozone research
1950	Visitor at Mass. Inst. Technol., MIT, USA
1962-1964	Researcher at the High Altitude Observatory in Boulder (CO, USA) Head of the Ozone Research Program at the newly founded NCAR (CO, USA)
1965-1985	Professor at ETH-Zurich
2004	Died on 27 Dec. in Zürich (Switzerland)

248

249 **Figure 5.** Biography of Hans-Ulrich Dütsch.

250

251 During Dütsch’s first years at ETHZ the main motivation for atmospheric ozone measurements at Arosa and  
252 Payerne was improving the understanding of the “high atmosphere” circulation patterns. This was with the aim  
253 of providing improved weather forecasts; the relationship between the vertical distribution of ozone and synoptic  
254 meteorological conditions was a major research topic in the 1960s and the early 1970s (see Breiland, 1964).  
255 Publications using measurements from the nearby Hohenpeissenberg Observatory (located in Bavaria, Southern  
256 Germany) revealed links between ozone levels and synoptic weather types (Hartmannsgruber, 1973;  
257 Attmannsgruber and Hartmannsgruber, 1973, 1975).

258 Stratospheric ozone depletion resulting from anthropogenic emissions was first publicized in the 1970s. Molina  
259 and Rowland (1974) and Stolarski and Cicerone (1974) independently discovered that chlorine radicals destroy

260 stratospheric ozone in a chain reaction. Furthermore, Molina and Rowland postulated that chlorofluorocarbons  
261 were a possible source gas for stratospheric chlorine. The chemical industry, with market leader DuPont,  
262 strongly objected to the view of Molina and Rowland. DuPont went so far as to launch an advertisement in the  
263 New York Times in 1975 stating that “Should reputable evidence show that some fluorocarbons cause a health  
264 hazard through depletion of the ozone layer, we are prepared to stop production of the offending compounds”.  
265 This provided a new justification for making high quality total ozone measurements, namely as a basis for  
266 reliable long-term trend analysis. This was a new challenge for making ground-based total ozone measurements  
267 since stratospheric ozone (in extratropics) can vary by as much as  $\pm 20\%$  from day to day, whereas  
268 anthropogenic stratospheric ozone changes were (and still are) on the order of only a few percent per decade.

269 Dütsch was one of the few scientists making important contributions to ozone research both before and after the  
270 debate on anthropogenic ozone depletion had started. Prior to this, Dütsch was largely curiosity-driven and had  
271 been interested in better understanding stratospheric ozone climatologies. For example, Dütsch (1974) provided  
272 basic science that served later to validate numerical simulations of anthropogenic ozone depletion. He also  
273 contributed to the IO3C, serving as member from 1957-1961, as secretary for 15 years (1961-1975), before being  
274 elected as president (1975-80), and being named an honorary member in 1984. He was also the main organizer  
275 of two important ozone symposia (the Quadrennial Ozone Symposia, organized for the IO3C) that took place in  
276 Arosa in 1961 and 1972. For more information on Dütsch’s research, see also Staehelin et al. (2016).

277

#### 278 **4.2 Ozone measurements at LKO under Dütsch**

279

280 In 1956, Dütsch was able to find resources to put the Umkehr ozone measurements in Arosa on a regular,  
281 operational basis. When Gertrud Perl had to leave Arosa in 1962 because of health problems, Dütsch took the  
282 responsibility and scientific leadership of the LKO, although he was at that time still living in Boulder (CO,  
283 USA). A large part of the observations, particularly the Umkehr measurements, were performed by students,  
284 under the tutelage of Perl and others, until Kurt Aeschbacher became responsible for the LKO measurements in  
285 1964, remaining so until November 2001. When Dütsch became professor at ETHZ in 1965, financial support of  
286 measurements at LKO (total ozone and Umkehr) continued as before (i.e., via KVV Arosa and Arosa  
287 municipality). In addition to the spectrophotometric measurements, Dütsch initiated ozone sonde measurements,  
288 which allowed obtaining detailed information on the ozone vertical profile. In 1966/67, these balloon  
289 measurements were operating from Kilchberg (close to Zürich), and were taken over in August 1968 by  
290 MeteoSwiss and made from Payerne, 140 km Southwest of Zürich, on the Swiss plateau (Jeannet et al., 2007).  
291 Since then, Payerne has become a member of “The Global Climate Observing System (GCOS) Reference  
292 Upper-Air Network” (GRUAN), which is an international observing network - under the auspices of WMO - of  
293 sites measuring essential climate variables above Earth's surface.

294 When Dütsch was responsible for the LKO, total ozone and Umkehr measurements were routinely performed  
295 using two Dobson spectrophotometers (see Fig. 4). To obtain the total ozone, only direct sun observations were  
296 performed. Dütsch applied the statistical Langley plot method to update the instrumental constants of the Dobson  
297 instruments every year (Dütsch, 1984). To apply the statistical Langley plot method a large number of ozone  
298 observations with different solar angles is required and therefore the observers need to choose suitable

299 meteorological conditions, e.g. cloud free conditions lasting for at least several minutes. Each year Dütsch went  
300 to Arosa for several days to check all the total ozone measurements for reliability and to apply the statistical  
301 Langley plot method. This led to small corrections being made to the total ozone measurements for the previous  
302 year and some small changes to the instrumental constants for the following year. Students, who usually stayed  
303 in Arosa for several months at a time, made the Umkehr measurements, which need to be started prior to sunrise  
304 every morning.

305 In 1973, the LKO measurements were moved from the “Florentinum” to “Haus Steinbruch” (see Fig. 2), at a  
306 distance of a few hundred meters. The working conditions at the LKO were much better at “Haus Steinbruch”  
307 than at the “Florentinum”, however the running costs were more expensive (for more detail see Staehelin and  
308 Viatte, in prep.). In 1978, the first international intercomparison of Dobson spectrophotometers took place in  
309 Arosa. This was organized by Dütsch under the auspices of WMO. The results of this first intercomparison  
310 exercise at Arosa were not satisfying, e.g. as “differences between (standard) instruments led to a debate as to  
311 which should be used as the standard for the intercomparison” (see Staehelin et al., 1998a). However, this debate  
312 only deepened the insight how necessary such comparisons are, fostering the reputation of Swiss ozone research.  
313 Dütsch continued to apply the statistical Langley plot method to update the instrumental constants.

## 314 **5. Period 1985-1988: Second intermediate period**

315

### 316 **5.1. International development and the importance of the Arosa total ozone time series**

317

318 In the early 1980s, as new information about reaction rate constants in ozone chemistry became available, it  
319 seemed that chemical ozone depletion by ODSs was considerably less than had been predicted in the late 1970s  
320 (Benedick, 1991). However, in 1985 the Antarctic ozone hole was discovered (Farman et al., 1985), and the  
321 international ozone research community was able to demonstrate that the ozone hole was caused by the chlorine  
322 and bromine in halocarbons, which were largely of anthropogenic origin. New insight came through the  
323 discovery (Solomon et al., 1986) that the chlorine and bromine species are very efficiently converted into ozone  
324 destroying forms on the surface of polar stratospheric cloud particles, acting as efficient catalysts in the cold  
325 polar stratospheric vortex (for reviews see Rowland, 1991; Peter, 1997; Solomon, 1999).

326 In the mid-latitudes, the first analysis based on the by then still relatively short record of measurements by the  
327 Total Ozone Mapping Spectrometer (TOMS) instrument onboard the Nimbus 7 satellite also showed rapid ozone  
328 decline (Heath, 1988). However, ground-based total ozone measurements such as those made using Dobson  
329 instruments did not confirm the large downward trends suggested by the satellite data. (Data from most ground  
330 stations are deposited in the international data archive (presently World Ozone and Ultraviolet data center  
331 (WOUDC), presently operated by Environment and Climate Change Canada). This discrepancy led to the 1988  
332 publication of the International Ozone Trend Panel report (IOTP, 1988). The report demonstrated that TOMS  
333 data available at the time were not reliable enough for trend analysis because of inappropriate treatment of the  
334 degradation of the diffuser plate. Later these data were reanalyzed more extensively using additional  
335 wavelengths in the retrieval algorithms and results were significantly improved (Stolarski et al., 1991). It turned  
336 out that also some of the data from the ground-based instruments were not of high enough quality to carry out

337 reliable long-term trend analyses. This was attributed to calibration issues with the Dobson instruments, which  
338 showed frequent sudden changes when compared to TOMS overpass data (IOTP, 1988). Rumen Bojkov,  
339 Secretary of the IO3C (1984-2000), used TOMS data to provide “provisionally revised” ground based  
340 measurements, which, however, had weaknesses such as not correcting for sulfur dioxide (SO<sub>2</sub>) interferences  
341 leading to potential errors in ozone trends based on Dobson series (e.g., De Muer and De Backer, 1992).

342 The most important application of the long-term measurements from Arosa (see Fig. 6) was probably their use in  
343 the 1988 IOTP report. The Arosa time series was the only Dobson dataset that required no correction and was  
344 much longer than any of the other ground-based measurement records. Results from Neil Harris’s PhD thesis  
345 were published in the IOTP and showed, for the first time, significant decreases in stratospheric ozone in the  
346 northern mid-latitude winter season (Harris, 1989). He used two different approaches, namely (1) dividing the  
347 individual records into two periods of similar length using measurements going back to 1957 and (2) developing  
348 a novel multiple linear regression model taking into account trends for different months. In this model the  
349 downward trend started in 1970, and the analyses also showed that the negative trend was not sensitive to the  
350 start year. At present, standard Dobson measurements are based on observations of two (AD) wavelength pairs,  
351 which allow to minimize the interference by aerosols, a technique introduced during the International  
352 Geophysical Year (IGY) in 1957-58. To further support his main conclusion, Harris (1989) also used single  
353 other wavelength pair (C) data from Arosa, which are available as representative (homogenized) measurements  
354 since 1931. Again, he found similar negative total ozone trends at most other sites in the northern mid-latitudes  
355 (IOTP, 1988).

356

357

358

359 **Figure 6.** Annual mean total column ozone values measured at the world’s longest continuous  
360 spectrophotometer site in Arosa, Switzerland, from 1926-present. The ozone column in Dobson units, where 100  
361 DU correspond to a 1-mm thick slab of pure ozone gas at standard conditions (273.15 K, 1000 hPa).

362

363 **5.2. Continuation of measurements at the LKO**

364

365 After Dütsch's retirement in 1985, the continuation of Swiss long-term ozone measurements again became  
366 uncertain. The professor succeeding Dütsch focused on another research topic, and consequently the ETH Zürich  
367 argued that the continuation of operational ozone measurements did not fall under the responsibility of a  
368 university. Conversely, MeteoSwiss, which already was responsible for the ozonesonde measurements since  
369 1968, argued that such long-term measurements needed scientific analysis by a well-qualified scientist, which  
370 MeteoSwiss was not able to support (a hiring freeze for permanent positions existed at the federal level at the  
371 time). Dütsch again wrote a letter to the responsible minister of the Federal government to point out the  
372 importance of the Arosa ozone measurements. Representatives from the Swiss Federal Office for the  
373 Environment (the "Swiss EPA") argued that ozone research in Switzerland needed to be continued since expert  
374 ozone researchers served a vital role to provide advice to policy makers regarding both stratospheric (in terms of  
375 the Vienna Convention and Montreal Protocol) and tropospheric ozone. Subsequently, a commission of the  
376 Swiss academy of Natural Sciences was tasked to analyze the situation. Government representatives as well as  
377 Swiss ozone researchers were invited to their meeting. Again, it was considered whether it made sense to move  
378 the LKO measurements to Davos (PMOD), but no decision was made in this regard. Nevertheless, MeteoSwiss  
379 and the ETH Zürich (i.e. IAC, Institute for Atmospheric and Climate Science, Laboratory of Atmospheric  
380 Physics (LAPETH) prior to 2001) agreed to continue the measurements, with the former officially accepting to  
381 take responsibility for the continuation of the ozone measurements at Arosa (total ozone and Umkehr) as well as  
382 the ozonesondes launched from Payerne, and the IAC at ETH Zürich consenting to continue ozone research. The  
383 agreement - implying that the person responsible for the LKO operations was moved to a MeteoSwiss position,  
384 whereas the IAC filled a scientific position with a major focus on ozone research became effective at the  
385 beginning of 1988.

386 **6. Period 1988-2014: Ozone measurements and research at MeteoSwiss and IAC (ETHZ)**

387

388 **6.1. International Development: The Montreal Protocol**

389

390 Since 1988, the most important justification for ozone measurements at LKO Arosa (total ozone und Umkehr)  
391 and ozone sonde launches in Payerne has been the documentation of the effect of ODSs on the stratospheric  
392 ozone layer and the effectiveness of the Montreal Protocol. Chemical ozone depletion by ODSs is expected to  
393 evolve very similar to the evolution of Equivalent Effective Stratospheric Chlorine (EESC). EESC provides an  
394 estimate of the total amount of halogens in the stratosphere, calculated from emission of chlorofluorocarbon and  
395 related halogenated compounds into the troposphere (lower atmosphere) and their efficiency in contributing to  
396 stratospheric ozone depletion (hence "effective"), and by taking the higher ozone destructiveness of bromine  
397 appropriately into account (hence "equivalent"). EESC peaked in the second half of the 1990s and subsequently  
398 showed a slow decrease, which is attributable to the Montreal Protocol, but in its slowness dictated by the long  
399 lifetimes of the emitted substances (see Fig. 7a). Total ozone measurements at Arosa are broadly consistent with  
400 long-term evolution of EESC (Stahelin et al., 2016) showing record low values in the early 1990s (Fig. 7b). The  
401 recovery of the ozone layer is a slow process and the signal of any sort of turnaround in the Arosa total ozone

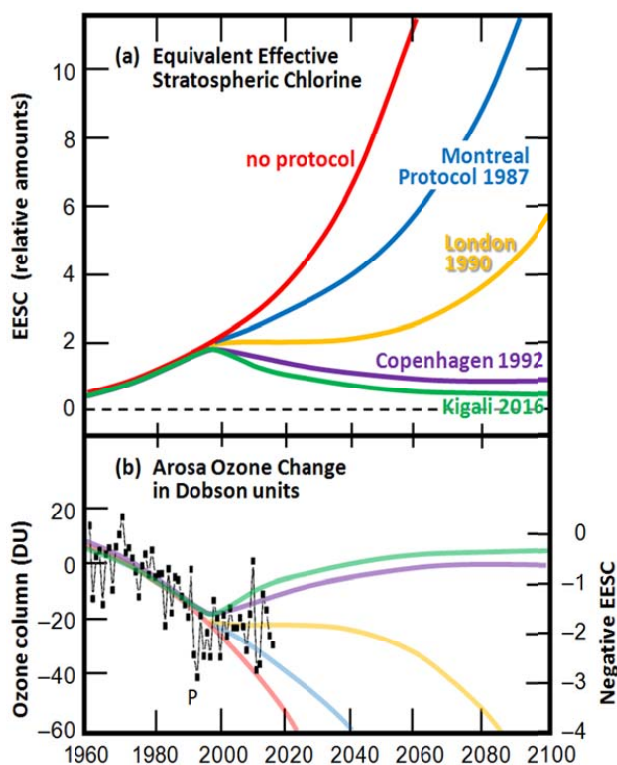

402 time series is still indistinct. Figure 7b shows the large interannual variability of the annual means, which is  
403 normal for a single measurement station and renders an attribution of the change in the downward trend difficult.  
404 While model results suggest that the Montreal Protocol and its amendments and adjustments have helped to  
405 avoid millions of additional skin cancer cases, Fig. 7b indicates that the global network of ozone station  
406 measurements needs to remain strong to in order to achieve a clear detection of the trend reversal and a proper  
407 attribution of the reasons.

408

409

410

411

412 **Figure 7.** (a) Relative abundance of Ozone Depleting Substances (ODSs, i.e. volatile halocarbons) expressed as  
413 equivalent effective stratospheric chlorine (EESC) for the mid-latitude stratosphere, shown for various scenarios  
414 (demonstrating the impact of the Montreal Protocol and its subsequent Adjustments and Amendments). EESC  
415 can be viewed as a measure of chemical ozone depletion by ODSs and takes into account the temporal emission  
416 of the individual ODS species as well as their ozone depleting potential. (b) Arosa annual mean ozone columns  
417 (black symbols, as in Fig. 6) in comparison with the scenarios in (a). “P” marks the eruption of Mt. Pinatubo  
418 1991, which has aggravated the ozone loss.

419

420

421 **6.2 LKO and related activities**

422

423 **6.2.1 Cooperation between MeteoSwiss and IAC (ETHZ)**

424 The cooperation between MeteoSwiss and the IAC of ETH Zürich ensured that the different strengths of the two  
425 institutions were fully utilized. MeteoSwiss had the expertise and resources to renew the infrastructure at the  
426 Arosa station and was also able to guarantee reliable long-term operation through permanent contracts for  
427 technicians and scientists. On the other hand, IAC (ETHZ) had the possibility to lead scientific research, for  
428 example, with PhD theses that produced results published in the scientific literature. The use of ozone  
429 measurements as basis for scientific research requires high quality data and the results from the ETH studies thus  
430 provided both, a feedback mechanism in terms of data quality and enhanced visibility of the ozone  
431 measurements.

432

433 **6.2.2 Renewal of the LKO infrastructure**

434 When Meteoswiss become responsible for the LKO ozone measurements in 1988, the instrument infrastructure  
435 required renewal and extension. This was completed under the leadership of Bruno Hoegger and included  
436 constructing a spectrodome to house the two Dobson spectrophotometers as well as semi-automation of the  
437 Dobson total ozone measurements and full automation of the Dobson Umkehr measurements (Hoegger et al.,  
438 1992). Three Brewer instruments were also purchased between 1988 and 1998, thus allowing increased  
439 reliability of the Arosa total ozone series by complementing the Dobson Umkehr measurements and by  
440 providing instrumental redundancy (see Fig. 4). Furthermore, additional UVB measurements were added. Stübi  
441 et al. (2017a) demonstrated the excellent stability of the Arosa Brewer triad over the past 15 years.

442

443 **6.2.3 Homogenization of the Arosa total ozone and Umkehr timeseries**

444 The Dobson instrument D15 was the main instrument used to measure total ozone in Arosa from 1949 to 1992  
445 (see Fig. 4). Archie Asbridge (formerly of Atmospheric Environment Canada) inspected this instrument after it  
446 was taken out of service in 1992, and it turned out that it had been operated in optical misalignment. Using the  
447 overlap between total ozone measurements of the D15 and D101 instruments, the latter of which was calibrated  
448 against the world standard instrument in 1986 and again in 1990, the Arosa column ozone time series was  
449 adjusted to the scale of the world primary Dobson instrument (for more detail see Staehelin et al., 1998a and  
450 Scarnato et al., 2010). The Arosa Umkehr timeseries also required homogenization (Zanis et al., 2006).

451

#### 452 **6.2.4 Foci of scientific studies since the 1990s**

453 The comparison of the unique Arosa total ozone timeseries from Dobson and Brewer instruments has allowed  
454 studies of the differences between the two instrument types (Stahelin et al., 1998a; Scarnato et al., 2009, 2010)  
455 as well as their long-term behavior since they are calibrated in different networks. In the 1990s, quantification of  
456 the downward ozone trends was the main reason for making long-term stratospheric measurements (comp.  
457 Section 5.1, and Stahelin et al., 1998b, 2001). These trends were seen as a consequence of increasing ODS  
458 concentrations. Subsequent studies were also devoted to understanding the potential contribution of other  
459 processes enhancing the observed downward trends, including long-term climate variability, e.g. in connection  
460 with tropopause altitude (Steinbrecht et al., 1998) and the North Atlantic Oscillation (NAO) or Arctic Oscillation  
461 (AO) (Appenzeller et al., 2000; Steinbrecht et al., 2001; Weiss et al., 2001). The unique length and high quality  
462 of the Arosa total ozone and Umkehr measurements also meant they were important for the EU project  
463 CANDIDOZ (Chemical and Dynamical Influences on Decadal Ozone Change; Zanis et al., 2006; Brunner et al.,  
464 2006; Harris et al., 2008). Later, as the ODS concentrations have decreased, documentation of the “turn around”  
465 in stratospheric ozone trends became more and more important (e.g. Mäder et al., 2010). The Arosa time series  
466 was also used to introduce the concept of extreme value theory in ozone science (Rieder et al., 2010a, b). This  
467 allowed to attribute extreme ozone values to events of various origins, such as dynamical factors as ENSO or  
468 NAO, or chemical factors, such as cold Arctic vortex ozone losses, or major volcanic eruptions of the 20<sup>th</sup>  
469 century, e.g. Mt. Pinatubo.

470

#### 471 **6.2.5 Tropospheric ozone**

472 The surface ozone measurements from Arosa are unique and very valuable for tropospheric chemistry studies.  
473 Surface ozone was measured already in the 1930s by Götz to quantify the contribution of tropospheric ozone to  
474 the total column, and later continued by the careful and representative surface ozone measurements made in the  
475 1950s (Götz and Volz, 1951; Perl, 1961). Thanks to these measurements it was possible to show that surface  
476 ozone concentrations increased by more than a factor of two from the 1950s to 1990 (Stahelin et al., 1994). This  
477 has commonly been attributed to the large increase in ozone precursor emissions (nitrogen oxides, volatile  
478 hydrocarbons, and carbon monoxide) resulting from the strong economic growth in industrialized countries  
479 following World War II. The surface ozone measurements made at Arosa and Jungfraujoch were pillars in the  
480 studies of Parrish et al., (2012, 2013), which contributed to an important report by the Task Force of the  
481 Hemispheric Transport of Air Pollution (HTAP). HTAP was organized in 2005 under the auspices of the United  
482 Nations Economic Commission for Europe (UNECE) Convention on Long-range Transboundary Air Pollution  
483 (LRTAP Convention) to study intercontinental transport of ozone in northern mid-latitudes. Based on these data,  
484 Parrish et al. (2014) compared three state-of-the-art chemistry climate models (CCMs) to show that simulated  
485 surface (baseline) ozone trends over Europe were about a factor two smaller than those seen in the available  
486 observations.

## 487 **7. Future of ozone measurements at the LKO**

### 488 **7.1 International Demands**

489

490 There is a general demand of proof of the effectiveness of the Montreal Protocol and a heads-up of how climate-  
491 related changes will affect the ozone layer, i.e. what the impacts are of the anticipated stratospheric cooling and  
492 the enhanced Brewer-Dobson circulation, and what this means for polar, mid-latitude and tropical ozone.

493 Recovery of the stratospheric ozone layer in response to the reduction of ODS concentrations controlled by the  
494 Montreal Protocol is slow (see Sect. 6.1) and requires continued long-term stratospheric ozone observations.  
495 ODSs most directly impact ozone in the upper stratosphere, where photolysis leads to the release of halogen  
496 radicals from these species. Extensive data analyses carried out under the auspices of the SI2N activity  
497 (commonly sponsored by SPARC (Stratosphere-troposphere Processes and their Role on Climate), IO3C,  
498 IGACO-O3/UV (Integrated Global Atmospheric Composition Changes), and NDACC) (Network for Detection  
499 of Atmospheric Composition Changes) highlighted issues related to the availability and uncertainty of  
500 measurements, such as of merged satellite datasets, and trend analysis techniques. (See the special journal issue  
501 jointly organized between Atmospheric Chemistry and Physics, Atmospheric Measurement Techniques, and  
502 Earth System Science Data: Changes in the vertical distribution of ozone – the SI2N report). Recently,  
503 Steinbrecht et al. (2017) presented the latest analysis of upper stratospheric ozone trends confirming the expected  
504 increase in upper stratospheric ozone in extratropics. It will be important to continue high quality stratospheric  
505 ozone measurements to be able to follow the slow recovery of the ozone layer in response to the changing  
506 burden of stratospheric ODSs, including nitrous oxide (N<sub>2</sub>O), which is likely to become the dominant species for  
507 stratospheric ozone depletion in future (Ravishankara et al., 2009; Portmann et al., 2012).

508 Climate change will modify the distribution of stratospheric ozone in different ways (see e.g. Arblaster et al.,  
509 2014). Increasing greenhouse gases cause decreasing stratospheric temperatures modifying reaction rates leading  
510 to increasing extratropical stratospheric ozone concentrations. At the same time, however, the polar stratospheres  
511 are not expected to cool on average. Furthermore climate change is expected to enhance the Brewer Dobson  
512 Circulation which transports ozone from the main tropical source region to the extra-tropics (Butchart, 2014).  
513 Modification of the Brewer Dobson Circulation is expected to increase stratospheric ozone in the mid-latitudes  
514 above levels of recovery in response to the decrease in ODSs alone. This has been termed “super recovery”. On  
515 contrast, the enhanced transport out of the tropics is expected to result in a decrease in stratospheric ozone in  
516 these regions. The enhancement of the Brewer Dobson Circulation is, however, still under debate, with state-of-  
517 the-art CCMs projecting an increase but only controversial observational evidence being available. Importantly,  
518 the expected enhancement depends strongly on the climate change scenario investigated, thus it is essential that  
519 high quality measurements are continued. The unique length of the Arosa timeseries is particularly useful for  
520 documenting the effects of climate change on ozone since the dataset covers a period of almost 40 years when  
521 the stratosphere was relatively undisturbed by anthropogenic influence, about 25 years in which anthropogenic  
522 ODSs increased in (stratospheric) concentration, and the latest period with the slow decrease of EESC. The  
523 Arosa timeseries will therefore play a crucial role in the coming decades to further document ozone changes in  
524 the Northern mid-latitudes, including the predicted “super recovery” expected to become important around 2030  
525 (e.g. Hegglin et al., 2015).

526

## 527 **7.2 Continuation of measurements at the LKO**

528

529 The MeteoSwiss board of directors decided in 2015 to explore the possibility of moving the Arosa measurements  
530 to the PMOD in Davos. Such a move could not only help to master financial restrictions, but might also offer the  
531 advantage of the excellent technical infrastructure, platforms and expertise that is available at PMOD in Davos.  
532 Within this program the Dobson instruments are currently completely automated (comp. Fig. 4). However, before  
533 such a move is to take place, an adequate period of overlapping measurements at both sites (Arosa and Davos) is  
534 essential. A break in the world's longest total ozone time series would be very unfortunate. However, the  
535 relocation is particularly challenging as stratospheric recovery from ODS is expected to be slow (see Sec. 6.1)  
536 leading to small ozone changes and requiring therefore measurements of very high quality (i.e. very high  
537 stability). At present simultaneous total ozone measurements of Brewer instruments of Dvaos and Arosa have  
538 been analyzed and presented (Stübi et al., 2017b)

## 539 8. Summary and Conclusions

540

541 Homogenous long-term records such as the total ozone record from Arosa are very valuable for trend analyses in  
542 climate science. Reliable long-term, ground-based total ozone measurements are also crucial for validation of  
543 ozone observations from space, particularly in terms of validating the long-term stability of merged satellite  
544 datasets (e.g. Labow et al., 2013). The extraordinary length of the Arosa record was particularly important for a  
545 wide range of studies, including the analysis of stratospheric ozone variability related to long-term climate  
546 variability such as NAO/AO (Appenzeller et al., 2000) and El Nino Southern Oscillation (Brönnimann et al.,  
547 2004) as well as the evaluation of the (early part of the) Twentieth Century Reanalysis Project (Compo et al.,  
548 2011; Brönnimann and Compo, 2012).

549 Justification for the LKO measurements changed from (1) study of environmental factors possibly important for  
550 the recovery from tuberculosis, to (2) study of air quality being an important natural resource in resort areas, to  
551 (3) enhancing understanding of atmospheric physics to improve weather forecasts, to (4) quantification of  
552 anthropogenic ozone destruction by ODSs, and finally to (5) document the effectiveness of the Montreal  
553 Protocol. In future, if stratospheric ozone gradually recovers as expected in response to the decreasing burden of  
554 ODSs, continued observations will be necessary to document the effects of climate change on stratospheric  
555 ozone, as predicted to by CCMs, i.e., through enhancement of the Brewer Dobson Circulation. The reasons for  
556 continuing the Arosa measurements have thus changed many times over the past decades. Initially it was never  
557 imagined that such a long record would have been made. A key element for this success was the motivation of  
558 the scientists and technicians involved: it appears that it was Götz's initiative that started field observations at  
559 Arosa, and twice the efforts of Dütsch were crucial in ensuring that measurements continued.

560 It is difficult to obtain funding for such continuous observations through normal science funding agencies such  
561 as the Swiss National Science Foundation (SNSF), since an additional few years of measurements usually do not  
562 result in novel scientific conclusions; this has been experienced by several other networks, for example, Network  
563 for Detection of Atmospheric Composition Changes (NDACC). The success of the Montreal Protocol probably  
564 contributed to the decrease in number of ozone measurements submitted to WOUDC that took place in the last  
565 years (Geir Braathen, personal communication). This might exacerbate in future as cost of monitoring cost are  
566 under pressure in many countries. However, we believe that such routine measurements are the responsibility of

567 developed countries. Institutions like national meteorological services, although they also may experience  
568 financial shortfalls, are ideally suited to carry out these types of measurements since they are (in contrast to  
569 universities) capable of making long-term commitments and have the possibility to hire permanent staff,  
570 something which is becoming more and more difficult at modern universities. Universities have the advantage of  
571 being able to focus on particular issues (e.g. through PhD theses) for a limited time, resulting in articles in peer-  
572 reviewed journals. Here it is important to stress the relevance of scientific activities using long-term  
573 observations. Excellent collaboration has existed between MeteoSwiss and IAC (ETHZ) for the past three  
574 decades, however, this particular type of cooperation seems less and less feasible in future as the permanent  
575 scientific position required to maintain this is no longer supported by ETHZ. In other countries the required  
576 research is integrated in the same institution (e.g. the German Weather Service (DWD) in Germany or the  
577 “Centre National de la Recherche Scientifique (CNRS)” in France) - a problem that still waits for proper solution  
578 for the Swiss longterm ozone measurements..

579 *Acknowledgements.* Several present and former colleagues from MeteoSwiss contributed to the study of the  
580 history of the LKO namely, Dr. Bruno Hoegger, Kurt Aeschbacher, and Herbert Schill. We acknowledge the  
581 help of Renzo Semadeni (Kulturarchiv Arosa-Schanfigg), Peter Bollier (retired teacher in history in the Alpine  
582 Mittelschule Davos and expert in the history of Fridericianum), Dr. Hans Ulrich Pfister (Staatsarchiv des  
583 Kantons Zürich), Susanne Wernli (Gemeindeverwaltung Davos), Simon Rageth and Florian Ambauen  
584 (Rhätische Bahn AG), Klaus Pleyer (German Sanatorium (Deutsche Heilstätte, today Hochgebirgsklinik Davos),  
585 Roesli Aeschbacher (wife of Kurt Aeschbacher), and several colleagues from the Swiss Federal Archives.  
586 Finally, we would like to thank Prof. Johannes Gartmann (medical director of Sanatorium Altein (1958-78) for  
587 valuable discussion, Dr. Wolfgang Steinbrecht (Observatorium Hohenpeissenberg of the German Weather  
588 Service (DWD) for helping to find literature related to ozone measurements and synoptic meteorology, and Bob  
589 Evans (formerly at NOAA, Boulder, USA) who supplied us with some information about the Dobson  
590 instruments operated at Arosa. We also want to thank to Rachel Vondach for drawing Figure 2.
