S.1 Exploration of PMF solutions

To understand the variability of our dataset we explored several constrained PMF solutions with a total of 4-10 factors. With a four-factor solution, a biomass burning OA (BBOA) factor was resolved exhibiting a high contribution of the fragment $C_2H_4O_2^+$, a typical marker for BBOA which originates from the pyrolysis of cellulose. In addition, this factor was significantly enhanced during winter which is expected due to the increased residential wood burning activity during this time of year in Magadino. However, the BBOA factor

15

included some sulphur-containing fragments which are not expected in such a profile. Meanwhile, Daellenbach et al., 2017, resolved for the first time a sulphur-containing factor (SCOA) with a similar off-line AMS analysis in their study about long-term chemical analysis of OA at 9 sites in Switzerland and Liechtenstein, including Magadino. In our case it seemed that SCOA was mixing with BBOA in this 4-factor solution. The other two factors included an oxygenated OA (OOA) with high contribution of the fragment CO_2^+ , but with no distinct yearly cycle and a factor with notable m/z 43 ($\text{C}_2\text{H}_3\text{O}^+$) and m/z 61 ($\text{C}_2\text{H}_5\text{O}_2^+$) signals enhanced in summer which seemed to be a mixing between a primary and a secondary OA factor. Bozzetti et al. in 2016 were the first to identify a primary biological OA (PBOA) factor whose mass spectrum resembled the mass spectra of plant debris and biological carbohydrates, with fragments like $\text{C}_2\text{H}_4\text{O}_2^+$ and $\text{C}_2\text{H}_5\text{O}_2^+$ being particularly enhanced. Such a factor is also expected at our measurement site, therefore a solution with higher number of factors could lead to such a separation.

A five-factor solution resulted in a reduction of the residuals and a clearer separation of the BBOA. However, PBOA and SCOA were still not clearly separated. A six-factor solution allowed for a segregation of the OOA into two different factors, with one showing increased concentrations during winter. Moreover, the SCOA could be better isolated, describing the variability of the CH_3SO_2^+ fragment and was dominant for the PM_{10} size fraction.

Yet, the PBOA factor was clearly identified with the introduction of a seventh factor which exhibited a distinct enhancement in the coarse fraction in spring and summer. This seven-factor solution resulted in a further decrease of the residuals and the resolution of three oxygenated factors. Two of which were named after their seasonal behaviour, winter and summer OOA (WOOA and SOOA), as proposed by Daellenbach et al., 2017. The third OOA exhibited a rather stable yearly cycle and high contribution of the m/z 44 (CO_2^+); see below in Fig. 5. As this factor is mainly fossil and correlates with fossil OC (as shown below in section 4.3), we name this factor fossil OOA (FOOA). Higher order solutions resulted in a further splitting of the oxygenated factors WOOA and OOA, which could not be interpreted. Hence, we selected this seven-factor solution.

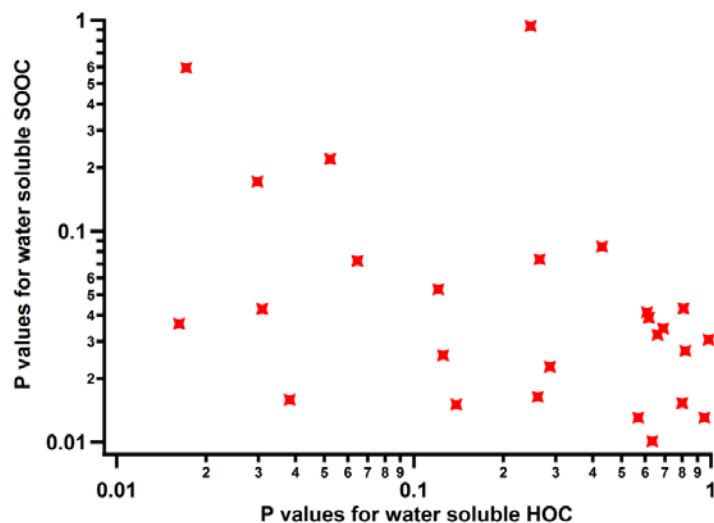

Figure S2. Scatter plot with p-values from the comparison of the two size fraction for the selected solutions of the factors SOOA and HOA. Some data points from the factors SOOA and HOA exhibited higher concentrations for the $\text{PM}_{2.5}$ size fraction compared to PM_{10} , which is not physically possible as aerosols collected by a PM_{10} inlet include also the $\text{PM}_{2.5}$ size fraction.

Table S1. P-value range

P value range	HOA	BBOA	PBOA	SCOA	OOA	SOOA	WOOA
Min	1.08E-05	4.00E-04	1.04E-06	1.30E-13	6.86E-10	8.02E-08	7.66E-3
Max	0.99	0.33	0.01	0.77	0.33	0.94	0.99

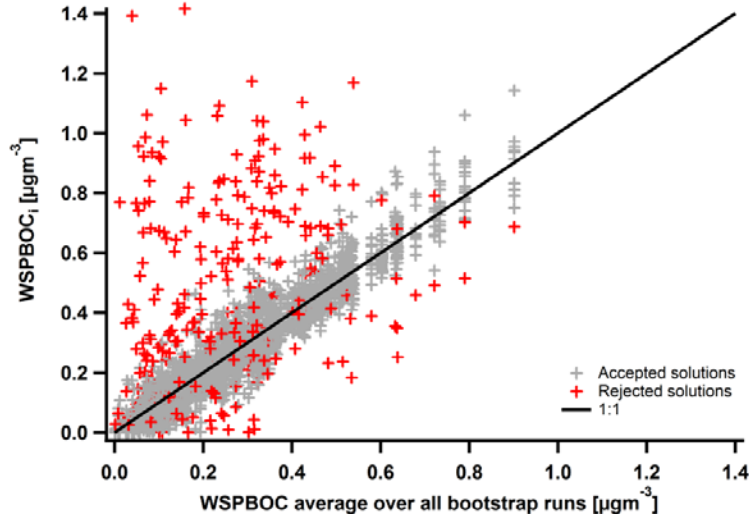

Figure S3. Example of a scatter plot between each bootstrap solution i and their average for the water soluble PBOA (WSPBOA) factor.

S.2 Recoveries weighting factor

- 5 To select the physically meaningful recoveries we applied a weighting factor f calculated by the following equation:

$$f = \begin{cases} 1 & , \text{for } 0 < R_{i,k,max} \leq 1 \\ \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(R_{i,k,max}-\mu)^2}{2\sigma^2}\right) & \\ \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(1-\mu)^2}{2\sigma^2}\right) & , \text{for } R_{i,k,max} > 1 \end{cases} \quad (S1)$$

Where $\sigma = 0.05$, $\mu = 1$, i the number of iterations and k the factor.

A visualisation of the weighting factor is shown in figure S4.
