12 **Abstract**

13 Observations of aerosol scattering and absorption offer valuable information about aerosol
14 composition. We apply a simulation of the Ultraviolet Aerosol Index (UVAI), a method of
15 detecting aerosol absorption from satellite observations, to interpret UVAI values observed by the
16 Ozone Monitoring Instrument (OMI) over 2005-2015 to understand global trends in aerosol
17 composition. We conduct our simulation using the vector radiative transfer model VLIDORT with
18 aerosol fields from the global chemical transport model GEOS-Chem. We examine the 2005-2015
19 trends in individual aerosol species from GEOS-Chem, and apply these trends to the UVAI
20 simulation to calculate the change in simulated UVAI due to the trends in individual aerosol
21 species. We find that global trends in the UVAI are largely explained by trends in absorption by
22 mineral dust, absorption by brown carbon, and scattering by secondary inorganic aerosol. Trends
23 in absorption by mineral dust dominate the simulated UVAI trends over North Africa, the Middle-
24 East, East Asia, and Australia. The UVAI simulation well resolves observed negative UVAI trends
25 over Australia, but underestimates positive UVAI trends over North Africa and Central Asia near
26 the Aral Sea, and underestimates negative UVAI trends over East Asia. We find evidence of an
27 increasing dust source from the desiccating Aral Sea, that may not be well represented by the
28 current generation of models. Trends in absorption by brown carbon dominate the simulated UVAI
29 trends over biomass burning regions. The UVAI simulation reproduces observed negative trends
30 over central South America and West Africa, but underestimates observed UVAI trends over
31 boreal forests. Trends in scattering by secondary inorganic aerosol dominate the simulated UVAI

32 trends over the eastern United States and eastern India. The UVAI simulation slightly
33 overestimates the observed positive UVAI trends over the eastern United States, and
34 underestimates the observed negative UVAI trends over India. Quantitative simulation of the OMI
35 UVAI offers new insight into global trends in aerosol composition.

36

37 **1. Introduction**

38 Atmospheric aerosols have significant climate impacts due to their ability to scatter and
39 absorb solar radiation and to their indirect effect through modification of cloud properties. The
40 exact magnitude of the direct radiative forcing remains highly uncertain (IPCC, 2014), although
41 most studies agree it is significant (Andreae and Gelencsér, 2006; Mann and Emanuel, 2006;
42 Mauritsen, 2016). Storelvmo et al. (2016) estimate that changes in global aerosol loading over the
43 past 45 years have caused cooling (direct and indirect) that masks about one third of the
44 atmospheric warming due to increasing greenhouse gas emissions. Aerosol absorption has been
45 estimated to be the second largest source of atmospheric warming after carbon dioxide
46 (Ramanathan and Carmichael, 2008; Bond et al., 2013; IPCC, 2014), although considerable
47 uncertainty remains regarding the exact magnitude (Stier et al., 2007). The large uncertainty
48 regarding the direct radiative impacts of aerosols on climate is driven by the large variability in
49 aerosol physical and chemical properties, as well as their various emission sources, making it
50 extremely difficult to fully understand their interactions with radiation (Pöschl, 2005; Moosmüller
51 et al., 2009; Curci et al., 2015; Kristiansen et al., 2016). Global observations of trends in aerosol
52 scattering and absorption would offer valuable constraints on trends in aerosol sources and
53 composition.

54 The emissions of aerosols and their precursors have changed significantly over the past
55 decade. In North America and Europe, the anthropogenic emissions of most aerosol species (e.g.
56 black carbon, organic aerosols) and aerosol precursors (e.g. sulfur dioxide and nitrogen oxides)
57 have decreased due to pollution controls (Leibensperger et al., 2012; Klimont et al., 2013; Curier
58 et al., 2014; Simon et al., 2014; Xing et al., 2015; Li et al., 2017a). By contrast, emissions of
59 aerosols and aerosol precursors have increased in developing countries due to increased industrial
60 activity, particularly in China and India. Chinese emissions of black carbon (BC), organic carbon
61 (OC), and nitrogen oxides (NO_x) have been increasing over the past decade (Zhao et al., 2013; Cui
62 et al., 2015), although in the most recent years NO_x emissions have been declining, driven by

63 denitration devices at power plants (Liu et al., 2016). Due to the wide implementation of flue-gas
64 desulfurization equipment on most power plants in China, emissions of sulfur dioxide (SO₂) in
65 some regions have been decreasing since about 2006-2008 (Lu et al., 2011; Wang et al., 2015;
66 Fioletov et al., 2016). Indian emissions of anthropogenic aerosols and their precursors have been
67 increasing over the past decade (Lu et al., 2011; Klimont et al., 2017). There have also been
68 significant changes in global dust and biomass burning emissions. Shao et al. (2013) use synoptic
69 data to estimate a global decrease in dust emissions between 1974 and 2012, driven largely by
70 reductions from North Africa with weaker contributions from Northeast Asia, South America, and
71 South Africa. By examining trends in burned area, Giglio et al. (2013) estimate a decrease in global
72 biomass burning emissions between 2000 and 2012. Trends in aerosol composition produced by
73 these changing emissions may be detectable from satellite observations of aerosol scattering and
74 absorption.

75 Detection of aerosol composition from passive nadir satellite observations is exceedingly
76 difficult; few methods exist. The aerosol-type classification provided by retrievals from the MISR
77 instrument, enabled by multi-angle viewing, is one such source of information about aerosol
78 composition from constraints on particle size, shape, and single scattering albedo (SSA) (Kahn
79 and Gaitley, 2015). MISR retrievals have been used to classify particles relating to events such as
80 biomass burning, desert dust, volcanic eruptions, and pollution events (e.g. Liu et al., 2007;
81 Kalashnikova and Kahn, 2008; Dey and Di Girolamo, 2011; Scollo et al., 2012; Guo et al., 2013).
82 The most commonly used satellite product for aerosol information is aerosol optical depth (AOD),
83 the columnar extinction of radiation by atmospheric aerosols. AOD can be retrieved from satellite
84 measurements of top of atmosphere radiance in combination with prior knowledge of aerosol
85 optical properties. Several studies have examined trends in satellite AOD. Following trends in
86 emissions, over the past decade positive trends in satellite AOD have been observed over Asia and
87 Africa corresponding to regions experiencing industrial growth (de Meij et al., 2012; Chin et al.,
88 2014a; Mao et al., 2014; Mehta et al., 2016), while negative trends in satellite AOD have been
89 observed over North America and Europe, largely due to pollution controls (Hsu et al., 2012; de
90 Meij et al., 2012; Chin et al., 2014b; Mehta et al., 2016). Studies such as these demonstrate the
91 information about the evolution of aerosol abundance offered by total column AOD retrievals,
92 however measurements of absorption would complement the scattering information in AOD
93 retrievals by providing independent information on aerosol composition.

94 The Ultraviolet Aerosol Index (UVAI) is a method of detecting aerosol absorption from
95 satellite measured radiances (Herman et al., 1997; Torres et al., 1998). Because the UVAI is
96 calculated from measured radiances, a priori assumptions about aerosol composition are not
97 required for its calculation, thus yielding independent information on aerosol scattering (Herman
98 et al., 1997; Torres et al., 1998, 2007; de Graaf et al., 2005; Penning de Vries et al., 2009) and
99 absorption. The UVAI has been widely applied to examine mineral dust (Israelevich et al., 2002;
100 Schepanski et al., 2007; Badarinath et al., 2010; Huang et al., 2010) and biomass burning aerosols
101 (Duncan et al., 2003; Guan et al., 2010; Torres et al., 2010; Kaskaoutis et al., 2011; Mielonen et
102 al., 2012), including brown carbon (Jethva and Torres, 2011; Hammer et al., 2016). The UVAI is
103 not typically used to examine scattering aerosol, however aerosol scattering causes a net decrease
104 in the overall value of the UVAI, meaning that the UVAI could be used to detect changes due to
105 both aerosol absorption and scattering. Prior interpretation of the UVAI has been complicated by
106 its dependence on geophysical parameters, such as aerosol layer height (Herman et al., 1997;
107 Torres et al., 1998; de Graaf et al., 2005). Examining trends in the UVAI would provide an exciting
108 opportunity to investigate the evolution of aerosol absorption and scattering over time, if the
109 multiple parameters affecting the UVAI could be accounted for through simulation.

110 In this work, we apply a simulation of the UVAI, which was developed and evaluated
111 regionally and seasonally in Hammer et al. (2016), to interpret trends in recently reprocessed OMI
112 UVAI observations for 2005-2015 to understand global changes in aerosol composition. We
113 interpret observed UVAI values by using a radiative transfer model (VLIDORT) to calculate
114 UVAI values as a function of simulated aerosol composition from the global 3-D chemical
115 transport model GEOS-Chem. Comparison of trends in observed OMI UVAI values to the trends
116 in simulated UVAI values, which are calculated using known aerosol composition, enables
117 qualification of how changes in aerosol absorption and scattering could influence the observed
118 UVAI trends and identification of model development needs. We conduct our analysis at the global
119 scale to understand trends worldwide. Section 2 describes the OMI UVAI observations and our
120 UVAI simulation. Section 3 examines the trends in emissions of GEOS-Chem aerosols and their
121 precursors for 2005-2015 to provide context for the trends in our simulated UVAI. Section 4
122 compares the mean values over 2005-2015 of the OMI UVAI and our simulated UVAI. Section 5
123 compares the 2005-2015 trends in OMI and simulated UVAI values. In section 6 we examine the
124 sensitivity of the UVAI to changes in the abundance of individual aerosol species. Trends in our

125 UVAI simulation are interpreted by applying the trends in the GEOS-Chem aerosol species to
126 calculate the associated change in UVAI. Section 7 reports the conclusions.

127

128 **2. Methods**

129 **2.1 OMI Ultraviolet Aerosol Index**

130 The OMI Ultraviolet Aerosol Index is a method of detecting absorbing aerosols from
131 satellite measurements in the near-UV wavelength region and is a product of the OMI Near-UV
132 algorithm (OMAERUV) (Herman et al., 1997; Torres et al., 1998, 2007). The OMAERUV
133 algorithm uses the 354 nm and 388 nm radiances measured by OMI to calculate the UVAI as a
134 measure of the deviation from a purely Rayleigh scattering atmosphere bounded by a Lambertian
135 reflecting surface. Positive UVAI values indicate absorbing aerosol while negative values indicate
136 non-absorbing aerosol. Near-zero values occur when clouds and Rayleigh scattering dominate.
137 Negative UVAI values due to aerosol scattering are often weak and have historically been affected
138 by noise in previous datasets (Torres et al., 2007; Penning de Vries et al., 2015). Because UVAI
139 values are calculated from top of atmosphere (TOA) radiance which contains total aerosol effects,
140 the presence (or lack) of scattering aerosol along with absorbing aerosol can either weaken (or
141 strengthen) the absorption signal. Therefore the UVAI could be used to detect changes over time
142 due to both aerosol absorption and scattering.

143 In this analysis, we carefully address UVAI error sources to enable quantitative analysis of
144 long term trends. We use a recently reprocessed version of the UVAI algorithm which treats clouds
145 with a Mie-scattering based water cloud model (Torres et al., 2018). This new dataset more
146 accurately accounts for scattering by mineral dust and by clouds, reducing systematic artifacts and
147 scan angle bias. We focus on cloud-filtered observations by excluding scenes with OMI UVAI
148 radiative cloud fraction exceeding 5% to further reduce uncertainty due to clouds. Since 2008 the
149 OMI observations have been affected by a row anomaly which reduces the sensor viewing
150 capability for specific scan angles ([http://projects.knmi.nl/omi/research/product/rowanomaly-
151 background.php](http://projects.knmi.nl/omi/research/product/rowanomaly-background.php)). The sudden suppression of observations for specific viewing geometries (i.e. the
152 row anomaly), could cause an additional spurious trend in the UVAI calculation. We reduce this
153 concern by using the recently reprocessed OMAERUV UVAI that is less sensitive to scan-angle
154 dependent cloud artifacts and by considering only scan positions 3-23 which remain unaffected by
155 the row anomaly. The monthly time series data are deseasonalized by subtracting the monthly

156 mean for the period 2005-2015 to focus on the long-term trend. Prior to regression, the data is
157 aggregated to monthly mean values, and each pixel is required to have data for at least 60% of the
158 time period in order for regression to be performed. We perform trend analysis on monthly mean
159 time series data for the years 2005-2015 using Generalized Least Squares (GLS) regression, as
160 described by Boys et al. (2014). An additional small, positive, spurious trend in the cloud-filtered
161 OMI UVAI remains which is believed to be due to instrumental effects (Torres et al., 2017). We
162 subtract this spurious global mean trend in the cloud-filtered UVAI prior to interpretation. In the
163 following section, we discuss our UVAI simulation and the implementation of the new UVAI
164 algorithm in the simulation.

165

166 **2.2 Simulated UVAI**

167 We simulate the UVAI using the VLIDORT radiative transfer model (Spurr, 2006),
168 following Buchard et al. (2015) and Hammer et al. (2016). We calculate the top of atmosphere
169 radiances at 354 nm and 388 nm needed for the UVAI calculation by supplying VLIDORT with
170 the OMI viewing geometry for each scene, as well as the GEOS-Chem simulation of vertical
171 profiles of aerosol extinction, spectrally dependent single scattering albedo, and the corresponding
172 spectrally dependent scattering phase function. Thus these parameters account for the sensitivity
173 of the UVAI to aerosol layer height and spectrally dependent aerosol optical properties.

174 We introduce to the UVAI simulation a Mie-scattering based water cloud model
175 (Deirmendjian, 1964) for consistency with the reprocessed OMI UVAI dataset. Following Torres
176 et al. (2018), we compute the radiances used in the UVAI calculation as a combination of clear
177 and cloudy sky conditions. We use the same cloud fractions and cloud optical depths used in the
178 OMI UVAI algorithm for coincident OMI pixels. We avoid cloudy scenes by considering only
179 pixels with OMI radiative cloud fraction of less than 5%. For the UVAI calculation we use the
180 surface reflectance fields provided by OMI. We calculated the 2005-2015 trends in these surface
181 reflectance fields, and found that they were statistically insignificant globally and on the order of
182 10^{-5} yr^{-1} . We calculated the change in UVAI due to a change in surface reflectance of this order of
183 magnitude, and found that the change in UVAI was negligible. We also calculated the change in
184 UVAI due to changes in simulated aerosol altitude, but found that the trends in aerosol altitude
185 were negligible (order $10^{-5} \text{ hPa yr}^{-1}$). Therefore we focus our analysis on trends in aerosol
186 composition which have a larger effect on the UVAI as demonstrated below.

187 We use the GEOS-Chem model v11-01 (<http://geos-chem.org>) as input to the UVAI
188 simulation, and to calculate the sensitivity of the UVAI simulation to aerosol composition. The
189 simulation is driven by assimilated meteorological data from MERRA-2 Reanalysis of the NASA
190 Global Modeling and Assimilation Office (GMAO). Our simulation is conducted at a spatial
191 resolution of $2^\circ \times 2.5^\circ$ with 47 vertical levels for the years 2005-2015. We supply VLIDORT with
192 GEOS-Chem aerosol fields coincident with OMI observations.

193 GEOS-Chem contains a detailed oxidant-aerosol chemical mechanism (Bey et al., 2001;
194 Park et al., 2004). The aerosol simulation includes the sulfate-nitrate-ammonium system
195 (Fountoukis and Nenes, 2007; Park et al., 2004; Pye et al., 2009), primary carbonaceous aerosol
196 (Park et al., 2003), mineral dust (Fairlie et al., 2007), and sea salt (Jaeglé et al., 2011). Semivolatile
197 primary organic carbon and secondary organic aerosol formation is described in Pye et al. (2010).
198 We update the original semi-volatile partitioning of secondary OA (SOA) formed from isoprene
199 with the irreversible uptake scheme in Marais et al. (2016). HNO_3 concentrations are reduced
200 following Heald et al. (2012). Aerosol optical properties are based on the Global Aerosol Data Set
201 (GADS) (Koepke et al., 1997) as originally implemented by Martin et al. (2003), with updates for
202 organics and secondary inorganics from aircraft observations (Drury et al., 2010), for mineral dust
203 (Lee et al., 2009; Ridley et al., 2012), and for absorbing brown carbon (Hammer et al., 2016). Here
204 we update the mineral dust optics at ultraviolet wavelengths using a refractive index that minimizes
205 the difference between the mean simulated and OMI UVAI values to allow focus on trends.
206 Aerosols are treated as externally mixed.

207 Anthropogenic emissions are from the EDGARv4.3.1 global inventory (Crippa et al., 2016)
208 with emissions overwritten in areas with regional inventories for the United States (NEI11; Travis
209 et al., 2016), Canada (CAC), Mexico (BRAVO; Kuhns et al., 2005), Europe (EMEP;
210 <http://www.emep.int/>), China (MEIC v1.2; Li et al., 2017a) and elsewhere in Asia (MIX; Li et al.,
211 2017a). Emissions from open fires for individual years from the GFED4 inventory (Giglio et al.,
212 2013) are included. The long-term concentrations from this simulation have been extensively
213 evaluated versus ground-based $\text{PM}_{2.5}$ composition measurements where available, and versus
214 satellite-derived $\text{PM}_{2.5}$ trends (Li et al., 2017b).

215 The Supplement evaluates trends in simulated SO_2 , NO_2 , and AOD versus satellite
216 retrievals from multiple instruments and algorithms. We find broad consistency between our
217 simulated NO_2 and SO_2 column trends with those from OMI (Figures S1 and S2). Our simulated

218 AOD trends are generally consistent with the trends in satellite AOD retrievals, except for positive
219 trends in AOD over western North America and near the Aral Sea in most retrieval products, and
220 a negative trend in AOD over Mongolia/Inner Mongolia in all retrieval products (Figure S3).

221 We filter our GEOS-Chem aerosol simulated fields based on the coincident OMI pixels,
222 which are regridded to the model resolution of $2^\circ \times 2.5^\circ$. This allows for the direct comparison
223 between our GEOS-Chem simulation and the OMI UVAI observations.

224

225 **3. Trend in emissions of GEOS-Chem aerosols and their precursors**

226 Figure 1 shows the trends in emissions of aerosols and their precursors from our GEOS-
227 Chem simulation calculated from the GLS regression of monthly time series values for 2005-2015.
228 Cool colors indicate negative trend values, warm colors indicate positive trend values, and the
229 opacity of the colors indicates the statistical significance of the trends. The trends in emissions of
230 sulfur dioxide (SO_2) and nitrogen oxides (NO_x) follow similar patterns (Figure 1a and 1b,
231 respectively). Negative trends (-1 to $-0.01 \text{ kg km}^{-2} \text{ yr}^{-1}$) are present over North America and
232 Europe, corresponding to pollution controls (Leibensperger et al., 2012; Klimont et al., 2013;
233 Curier et al., 2014; Simon et al., 2014; Xing et al., 2015; Li et al., 2017a). Positive trends (0.5 to 1
234 $\text{kg km}^{-2} \text{ yr}^{-1}$) in both species are present over India and eastern China, however the positive trends
235 in emissions of SO_2 over eastern China are interspersed with negative trends (-1 to -0.5 kg km^{-2}
236 yr^{-1}) in SO_2 emissions, corresponding to the deployment of desulfurization equipment on power
237 plants in recent years (Lu et al., 2011; Klimont et al., 2013; Wang et al., 2015). Ammonia (NH_3)
238 emissions (Figure 1c) have positive trends (0.001 to $0.05 \text{ kg km}^{-2} \text{ yr}^{-1}$) over most of South America,
239 North Africa, the Middle-East, and most of Asia with larger trends (0.1 to $0.5 \text{ kg km}^{-2} \text{ yr}^{-1}$) over
240 India and eastern China. There are positive trends (0.001 to $0.05 \text{ kg km}^{-2} \text{ yr}^{-1}$) in black carbon (BC)
241 emissions (Figure 1d) over North Africa, Europe, the Middle-East, India, and China, and negative
242 trends (-0.05 to $-0.001 \text{ kg km}^{-2} \text{ yr}^{-1}$) over North America, Europe, West Africa, and central South
243 America. The trends in primary organic aerosol (POA) emissions (Figure 1e) follow a similar
244 pattern as the trends in BC emissions, except there are negative trends (-0.1 to $-0.05 \text{ kg km}^{-2} \text{ yr}^{-1}$)
245 over eastern China, and the negative trends (-1 to $-0.1 \text{ kg km}^{-2} \text{ yr}^{-1}$) over West Africa and central
246 South America are larger in magnitude reflecting regional changes in fire activity (Chen et al.,
247 2013; Andela and van der Werf, 2014). There are also positive trends (0.001 to $0.05 \text{ kg km}^{-2} \text{ yr}^{-1}$)
248 over the northern United States and Canada. The trends in dust emissions (Figure 1f) show the

249 largest magnitude of all the various species, although many have low statistical significance, with
250 areas of positive and negative trends (> 1 and $< -1 \text{ kg km}^{-2} \text{ yr}^{-1}$) over North Africa, positive trends
251 ($> 1 \text{ kg km}^{-2} \text{ yr}^{-1}$) parts of the Middle-East, and negative trends ($< -1 \text{ kg km}^{-2} \text{ yr}^{-1}$) over northern
252 China and southern Australia.

253

254 **4. Mean UVAI values for 2005-2015**

255 We examine the seasonal long-term mean UVAI values for insight into the spatial
256 distribution of the aerosol absorption signals. Figures 2 and 3 show the seasonal mean UVAI values
257 for 2005-2015 for OMI and the simulation, respectively. Positive UVAI values between 0.2 and
258 1.5 indicating aerosol absorption are present over major desert regions globally for both OMI and
259 the simulation, particularly over the Saharan, Iranian, and Thar deserts. These positive signals are
260 driven by the absorption by mineral dust (Herman et al., 1997; Torres et al., 1998; Buchard et al.,
261 2015). The simulation underestimates some of the smaller dust features captured by OMI, such as
262 over western North America, South America, Australia, and parts of Asia, perhaps reflecting an
263 underestimate in the simulated mineral dust lifetime (Ridley et al. 2012) and missing dust sources
264 (Ginoux et al., 2012; Guan et al., 2016; Huang et al., 2015; Philip et al., 2017). The seasonal
265 variation in the observed and simulated UVAI is similar albeit with larger simulated values in
266 spring (MAM) over North Africa. In all seasons, the UVAI values driven by absorption by dust in
267 the simulation are concentrated mostly over North Africa, while for OMI the UVAI values are
268 more homogeneous over the Middle-East and Asia as well. Positive UVAI values of $\sim 0.2-1$ over
269 West and central Africa appearing in both the OMI and simulated values correspond to absorption
270 by brown carbon from biomass burning activities in these regions (Jethva and Torres, 2011;
271 Hammer et al., 2016). Over ocean most data are removed by our strict cloud filter.

272

273 **5. Trend in UVAI values between 2005-2015**

274 Figure 4 shows the trend in OMI and simulated UVAI values (coincidentally sampled from
275 OMI) calculated from the GLS regression of monthly UVAI time series values over 2005-2015.
276 Several regions exhibit consistency between the OMI and simulated UVAI trends. There are
277 statistically significant, positive trends in both OMI and simulated UVAI values over the eastern
278 United States (OMI: 1.0×10^{-5} to $2.5 \times 10^{-4} \text{ yr}^{-1}$, simulated: $2.5 \times 10^{-4} \text{ yr}^{-1}$ to $5.0 \times 10^{-4} \text{ yr}^{-1}$), and
279 Canada and parts of Russia (OMI: 1.0×10^{-5} to $2.5 \times 10^{-4} \text{ yr}^{-1}$, simulated: 5.0×10^{-4} to $2.0 \times 10^{-3} \text{ yr}^{-1}$).

280 Positive UVAI trends (1.0×10^{-5} to $2.5 \times 10^{-4} \text{ yr}^{-1}$) in both OMI and simulated values are present
281 over Europe, although the simulated trends have low statistical significance. Statistically
282 significant, positive UVAI trends (5.0×10^{-4} to $2.0 \times 10^{-3} \text{ yr}^{-1}$) in OMI values are apparent over
283 North Africa, which generally are captured by the simulation but with low statistical significance.
284 Negative UVAI trends ($-1.5 \times 10^{-3} \text{ yr}^{-1}$ to $-1.0 \times 10^{-5} \text{ yr}^{-1}$) in both OMI and simulated values are
285 apparent over most of South America, southern Africa, and Australia. Negative UVAI trends ($-$
286 2×10^{-3} to $-5.0 \times 10^{-4} \text{ yr}^{-1}$) in both OMI and simulated values are present over West Africa, with low
287 statistical significance that could be related to the filtering of persistent clouds. OMI and simulated
288 UVAI values show negative trends (-2×10^{-3} to $-5.0 \times 10^{-4} \text{ yr}^{-1}$) over India, although the simulated
289 trends have lower statistical significance.

290 Some regions have trends in OMI UVAI values which are not captured by the simulation.
291 Statistically significant, positive UVAI trends ($2.5 \times 10^{-4} \text{ yr}^{-1}$ to $1.5 \times 10^{-3} \text{ yr}^{-1}$) over the western
292 United States are apparent in the OMI values but not in the simulation. Zhang et al. (2017) found
293 positive trends in aerosol absorption optical depth from OMI retrievals that they attributed to
294 positive trends in mineral dust over the region, which were not captured by their GEOS-Chem
295 simulation. Statistically significant, positive UVAI trends (5.0×10^{-4} to $2.0 \times 10^{-3} \text{ yr}^{-1}$) in OMI
296 values exist over the Middle-East, while the simulation has negative trends with low statistical
297 significance. The OMI UVAI reveals a region of statistically significant, negative trends (-2×10^{-3}
298 to $-5.0 \times 10^{-4} \text{ yr}^{-1}$) over Mongolia/Inner Mongolia which is not captured by the simulation. There is
299 also a small area of statistically significant, positive UVAI trends (1.5×10^{-3} to $2.0 \times 10^{-3} \text{ yr}^{-1}$) in
300 OMI values of over Central Asia between the Caspian Sea and the Aral Sea which is not captured
301 by the simulation. Trends in surface reflectance from the diminishing Aral Sea cannot solely
302 explain the UVAI trends since they extend over the Caspian Sea. Trends in mineral dust are a more
303 likely explanation as discussed further below.

304 Figures 5 and 6 show the seasonality of the OMI and simulated UVAI trends respectively.
305 The positive UVAI trends over the eastern United States is strongest in summer (JJA) for both
306 OMI and the simulation. The positive UVAI trends over North Africa and the Middle-East are
307 present for all seasons for OMI and for most seasons in the simulation, except in JJA for North
308 Africa and spring (MAM) for the Middle-East. The simulation underestimates the observed UVAI
309 trend over North Africa in SON, perhaps related to an underestimate in trends in mineral dust
310 emissions in the simulation during this season. He et al. (2014) examined the 2000-2010 trends in

311 global surface albedo using the Global Land Surface Satellites (GLASS) dataset and found no
312 significant trends over this region during SON. The negative trend in UVAI values over West
313 Africa is most apparent in the fall (SON) and winter (DJF) for both OMI and the simulation. The
314 negative OMI UVAI trends over Mongolia/Inner Mongolia and the positive OMI UVAI trends
315 near the Aral Sea are strongest in JJA and weakest in DJF, providing evidence for a mineral dust
316 source. The OMI UVAI trend over Mongolia/Inner Mongolia may be part of a longer term trend.
317 Guan et al. (2017) examined dust storm data over northern China (including Inner Mongolia) for
318 the period 1960-2007, and found that dust storm frequency has been declining over the region due
319 to a gradual decrease in wind speed. The current generation of chemical transport models is
320 unlikely to represent the source near the Aral Sea without an explicit parameterization of the drying
321 sea. The desiccation of the Aral Sea over recent decades has resulted in a steady decline in water
322 coverage over the area (Shi et al., 2014; Shi and Wang, 2015) and has led to the dried up sea bed
323 becoming an increasing source of dust activity in the region (Spivak et al., 2012). Indoitu et al.
324 (2015) found that most dust events are directed towards the west, consistent with the OMI
325 observations. An increase in surface reflectance due to the drying up of the sea bed could also
326 positively influence trends in UVAI. He et al. (2014) found a positive trend over 2000-2010 in
327 surface albedo over the region in JJA and SON, corresponding to when the OMI UVAI trends are
328 strongest.

329

330 **6. Contribution of individual aerosol species to the simulated UVAI**

331 To further interpret the UVAI trends, we examine the trends in aerosol concentrations from
332 our GEOS-Chem simulation (Figure 7). Figure 7a shows the trends in secondary inorganic aerosol
333 (SIA). There are statistically significant, negative trends over the eastern United States (-1 to -0.05
334 $\mu\text{g m}^{-2} \text{yr}^{-1}$) and statistically significant, positive trends over the Middle-East (0.05 to 0.5 $\mu\text{g m}^{-2}$
335 yr^{-1}), India (0.05 to 1 $\mu\text{g m}^{-2} \text{yr}^{-1}$), South America, and southern Africa (0.05 to 0.25 $\mu\text{g m}^{-2} \text{yr}^{-1}$).
336 Figure 7b shows the trends in dust. Similar to the trends in emissions, the trends in dust
337 concentrations are of the largest magnitude of the various species, however often with low
338 statistical significance. There are positive trends over the Middle-East ($> 2 \mu\text{g m}^{-2} \text{yr}^{-1}$), India (0.05
339 to 2 $\mu\text{g m}^{-2} \text{yr}^{-1}$), and north west China (1 to 2 $\mu\text{g m}^{-2} \text{yr}^{-1}$). There are also positive trends (0.05 to
340 0.25 $\mu\text{g m}^{-2} \text{yr}^{-1}$) with low statistical significance over the United States, northern South America,
341 southern Africa, and northern Australia. There is a combination of positive and negative trends ($>$

342 2 and $< -2 \mu\text{g m}^{-2} \text{yr}^{-1}$) over North Africa, and negative trends over China and Mongolia ($< -2 \mu\text{g}$
343 $\text{m}^{-2} \text{yr}^{-1}$) and Australia (-1 to $-0.5 \mu\text{g m}^{-2} \text{yr}^{-1}$). Figures 7c and 7d show the trends in total organic
344 aerosol (OA) and the absorbing brown carbon (BrC) component of OA, respectively. Positive
345 trends over Canada and parts of Russia (0.05 to $0.5 \mu\text{g m}^{-2} \text{yr}^{-1}$) in total OA are mainly due to the
346 positive trend in BrC. Statistically significant, negative trends in total OA (-1 to $-0.05 \mu\text{g m}^{-2} \text{yr}^{-1}$)
347 over the eastern United States are dominated by scattering organic aerosol. Statistically significant,
348 negative trends (-2 to $-0.05 \mu\text{g m}^{-2} \text{yr}^{-1}$) over West Africa and South America for total OA are
349 dominated by the trend in absorbing BrC. Figures 5e and 5f show the trends in black carbon (BC)
350 and salt, respectively. There are positive trends (0.05 to $0.25 \mu\text{g m}^{-2} \text{yr}^{-1}$) in BC with low statistical
351 significance over India and China. Sea salt trends are negligible.

352 To gain further insight into how changes in aerosols effect the trends in simulated UVAI,
353 we examine the sensitivity of the UVAI to changes in individual aerosol species. Figure 8 shows
354 the change in annual mean UVAI due to doubling the concentration of individual aerosol species.
355 This information facilitates interpretation of the observed UVAI trends by identifying the chemical
356 components that could explain the observed trends. Doubling scattering SIA concentrations
357 (Figure 8a) decreases the UVAI between -0.25 and -0.1 over most of the globe, with the largest
358 changes over the Eastern United States, Europe, parts of the Middle-East, India, and south east
359 China. Doubling dust concentrations (Figure 8b) produces the largest changes in UVAI, causing
360 increases between 0.5 and 1 over North Africa, and smaller increases between 0.2 and 0.5 over the
361 Middle-East, Europe, and parts of Asia and Australia. Figures 8c and 8d show the changes in
362 UVAI due to doubling total OA concentrations and the absorbing BrC component, respectively.
363 The doubling of BrC increases the UVAI between 0.1 and 0.5 over Canada, West and central
364 Africa, India, parts of Russia, eastern China, and central South America. Doubling total OA
365 concentrations over central South America causes a net decrease of ~ -0.1 as the scattering
366 component of total OA cancels out the absorption by BrC. Doubling BC concentrations (Figure
367 8e) increases the UVAI of 0.1 over central Africa, India, and south east China, while doubling sea
368 salt concentrations (Figure 8f) has negligible effect on the UVAI.

369 Figure 9 shows the change in simulated UVAI due to the 2005-2015 trends in individual
370 aerosol species from our GEOS-Chem simulation. The change for each species is calculated by
371 applying the aerosol concentration trends for the individual aerosol type while leaving the
372 concentrations unchanged for the other aerosol species, then taking the difference between this

373 perturbed UVAI simulation and an unperturbed simulation. Negative trends in scattering SIA
374 (Figure 9a) increase the UVAI by 1.0×10^{-4} to $7.5 \times 10^{-3} \text{ yr}^{-1}$ over the eastern United States and by
375 1.0×10^{-4} to $2.5 \times 10^{-3} \text{ yr}^{-1}$ over Europe, corresponding to regions of positive UVAI trends in both
376 OMI and the simulation (Figure 4). Increasing SIA decreases the UVAI by $-2.5 \times 10^{-3} \text{ yr}^{-1}$ to $-$
377 $1.0 \times 10^{-4} \text{ yr}^{-1}$ over the Middle-East, India, and east China. Trends in dust concentrations (Figure
378 9b) cause the largest change in UVAI with regional increases $> 1 \times 10^{-2} \text{ yr}^{-1}$ and regional decreases
379 $< -1 \times 10^{-2} \text{ yr}^{-1}$. Simulated UVAI trends due to mineral dust are mostly negative over North Africa,
380 East Asia, and Australia, while mostly positive over the Middle-East. Noisy trends in regional
381 meteorology cause heterogeneous trends in dust and in the UVAI, with low statistical significance.
382 Figures 9c and 9d show the change in UVAI due to the trends in total OA and the absorbing BrC
383 component of total OA, respectively. Most of the changes in UVAI due to the trends in total OA
384 are caused by the trends in the absorbing BrC component, with increases in the UVAI between
385 2.5×10^{-3} and $1 \times 10^{-2} \text{ yr}^{-1}$ over Canada and parts of Russia, corresponding to regions of positive
386 UVAI trends for both OMI and the simulation (Figure 4). There are decreases in the UVAI $< -$
387 $1 \times 10^{-2} \text{ yr}^{-1}$ over central South America and West Africa due to the negative trends in BrC,
388 corresponding to regions of negative UVAI trends for both OMI and the simulation (Figure 4).
389 Over the eastern United States there is a mixture of increases and decreases in the UVAI due to
390 the trends in scattering organic aerosol. Positive trends in BC increase the UVAI (Figure 9e) by
391 1.0×10^{-4} to $2.5 \times 10^{-3} \text{ yr}^{-1}$ over India and China. There are no obvious changes in the UVAI due to
392 the trends in sea salt (Figure 9f).

393

394 **7. Conclusions**

395 Observations of aerosol scattering and absorption offer valuable information about aerosol
396 composition. We simulated the Ultraviolet Aerosol Index (UVAI), a method of detecting aerosol
397 absorption using satellite measurements, to interpret trends in OMI observed UVAI over 2005-
398 2015 to understand global trends in aerosol composition. We conducted our simulation using the
399 vector radiative transfer model VLIDORT with aerosol fields from the global chemical transport
400 model GEOS-Chem.

401 We examined the 2005-2015 trends in individual aerosol species from GEOS-Chem, and
402 applied these trends to the UVAI simulation to calculate the change in simulated UVAI due to the
403 trends in individual aerosol species. We found that global trends in the UVAI were largely

404 explained by trends in absorption by mineral dust, absorption by brown carbon, and scattering by
405 secondary inorganic aerosols. The two most prominent positive trends in the observed UVAI were
406 over North Africa and over Central Asia near the desiccating Aral Sea. The simulated UVAI
407 attributes the positive trends over North Africa to increasing mineral dust, despite an
408 underestimated simulated trend in fall (SON) that deserves further attention. The positive trends
409 in the observed UVAI over Central Asia near the shrinking Aral Sea are likely due to increased
410 dust emissions, a feature that is unlikely to be represented in most chemical transport models. The
411 most prominent negative trends in the observed UVAI were over East Asia, South Asia, and
412 Australia. The simulation attributed the negative trends over East Asia and Australia to decreasing
413 mineral dust, despite underestimating the trend in East Asia. The simulation attributed the negative
414 trend over South Asia to increasing scattering secondary inorganic aerosols, a trend that the
415 observations imply could be even larger. We found the positive trends in the UVAI over the eastern
416 United States that were strongest in summer (JJA) in both the observations and the simulation were
417 driven by negative trends in scattering secondary inorganic aerosol and organic aerosol. Observed
418 negative trends in winter (DJF) were less well simulated. Over West Africa and South America,
419 negative trends in UVAI were explained by negative trends in absorbing brown carbon. Thus,
420 trends in the observed UVAI offer valuable information on the evolution of global aerosol
421 composition that can be understood through quantitative simulation of the UVAI. Looking
422 forward, the availability of the UVAI observations from 1979 to the present offer a unique
423 opportunity to understand long-term trends in aerosol composition. The recent launch of the
424 TROPOspheric Monitoring Instrument (TROPOMI; Veefkind et al., 2012) and the forthcoming
425 geostationary constellation offer UVAI observations at finer spatial and temporal resolution. The
426 forthcoming Multi-Angle Imager for Aerosols (MAIA; Diner et al., 2018) satellite instrument
427 offers an exciting opportunity to derive even more information about aerosol composition by
428 combining measurements at ultraviolet wavelengths with multi-angle observations and
429 polarization sensitivity.

795

796 **Figures**

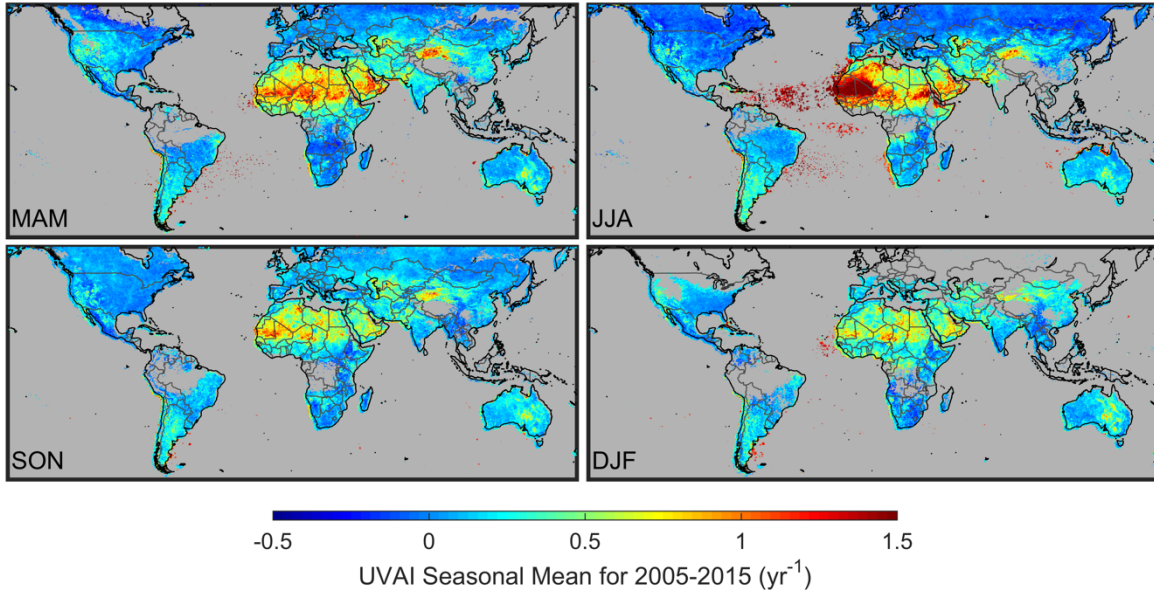

797

798

799 **Figure 1:** Trend in emissions of a) sulfur dioxide (SO₂) (kg SO₂ km⁻² yr⁻¹), b) nitrogen oxides
800 (NO_x) (kg NO km⁻² yr⁻¹), ammonia (NH₃) (kg NH₃ km⁻² yr⁻¹), black carbon (BC) (kg C km⁻² yr⁻¹),
801 primary organic carbon (POA) (kg C km⁻² yr⁻¹), and dust (kg km⁻² yr⁻¹) used in our GEOS-Chem
802 simulation. The trends are calculated from the Generalized Least Squares regression of monthly
803 time series values over 2005-2015.

804

805

806 **Figure 2:** Seasonal mean UVAI values for the 2005-2015 period as observed by OMI for MAM
 807 (May, April, March), JJA (June, July August), SON (September, October, November), and DJF
 808 (December, January, February). Gray indicates persistent cloud fraction greater than 5%.

809

810

811

812

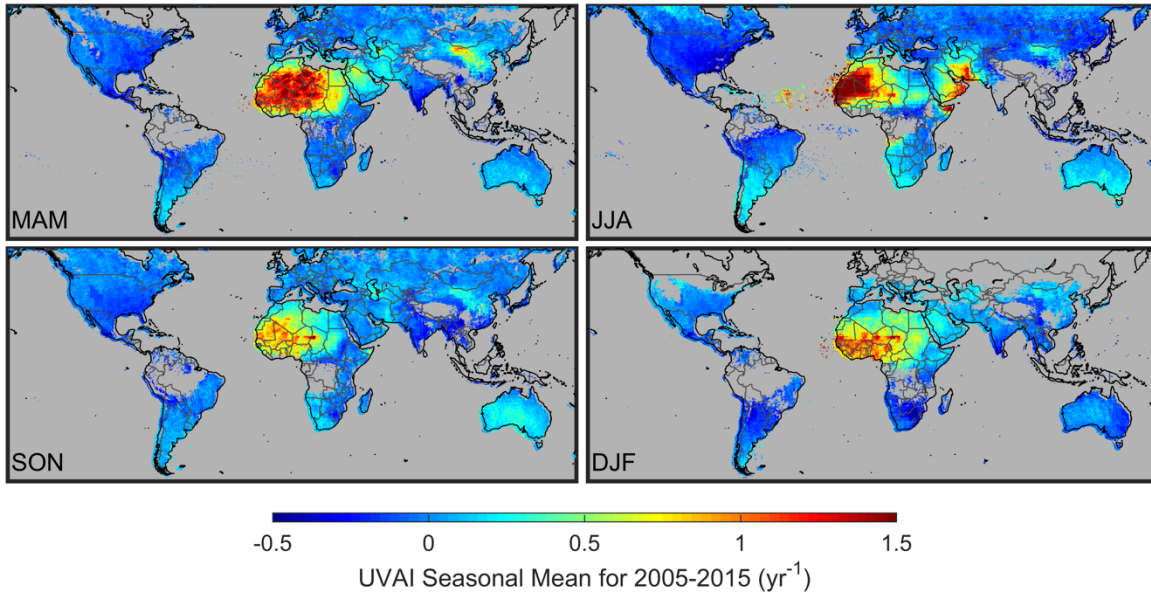

813

814

815

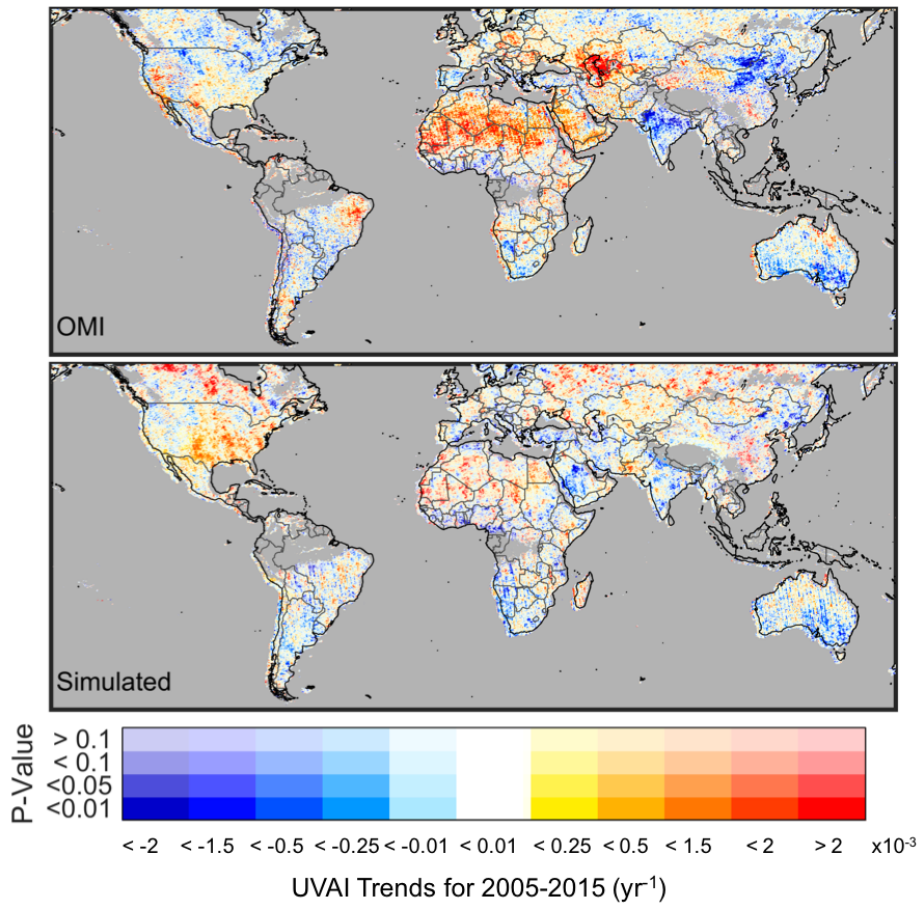

816

817

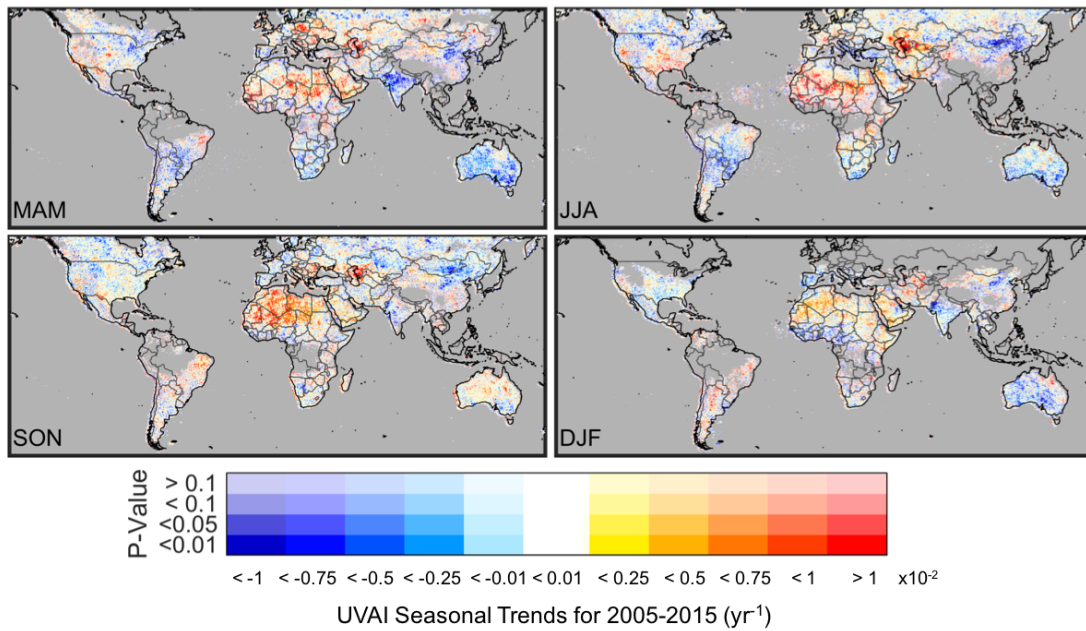

818

819 **Figure 3:** Seasonal mean UVAI values for the 2005-2015 period from our simulation coincidentally
 820 sampled from OMI for MAM (May, April, March), JJA (June, July August), SON (September,
 821 October, November), and DJF (December, January, February). Gray indicates persistent cloud
 822 fraction greater than 5%.

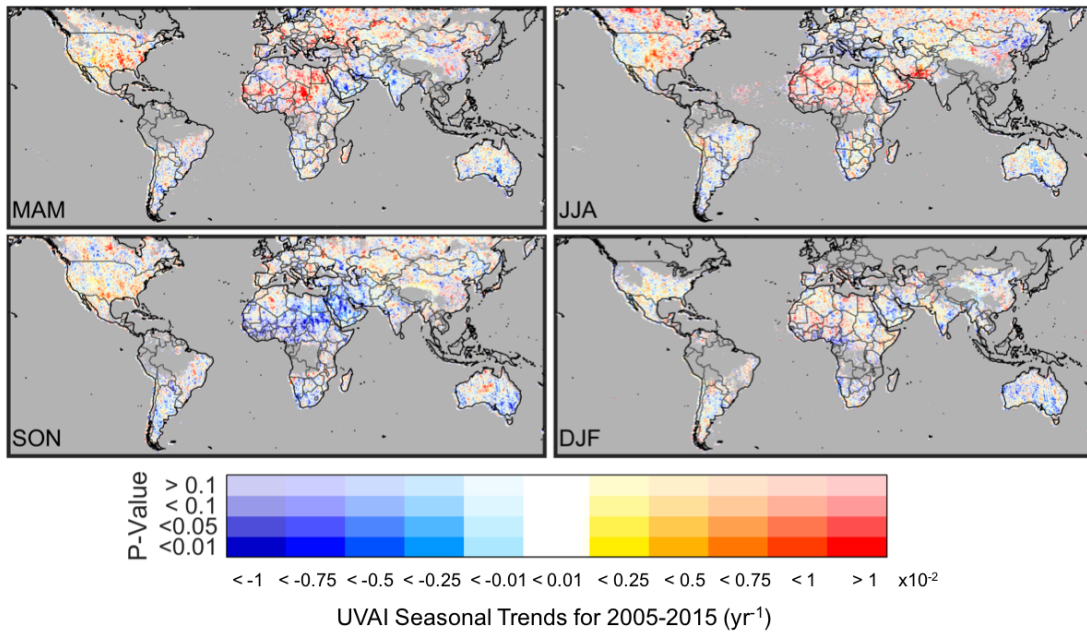

823

824 **Figure 4:** Trends in OMI (top panel) and simulated (bottom panel) UVAI values coincidentally
 825 sampled from OMI calculated from the Generalized Least Squares regression of monthly time
 826 series values over 2005-2015. The opacity of the colors indicates the statistical significance of the
 827 trend. Gray indicates persistent cloud fraction greater than 5%.

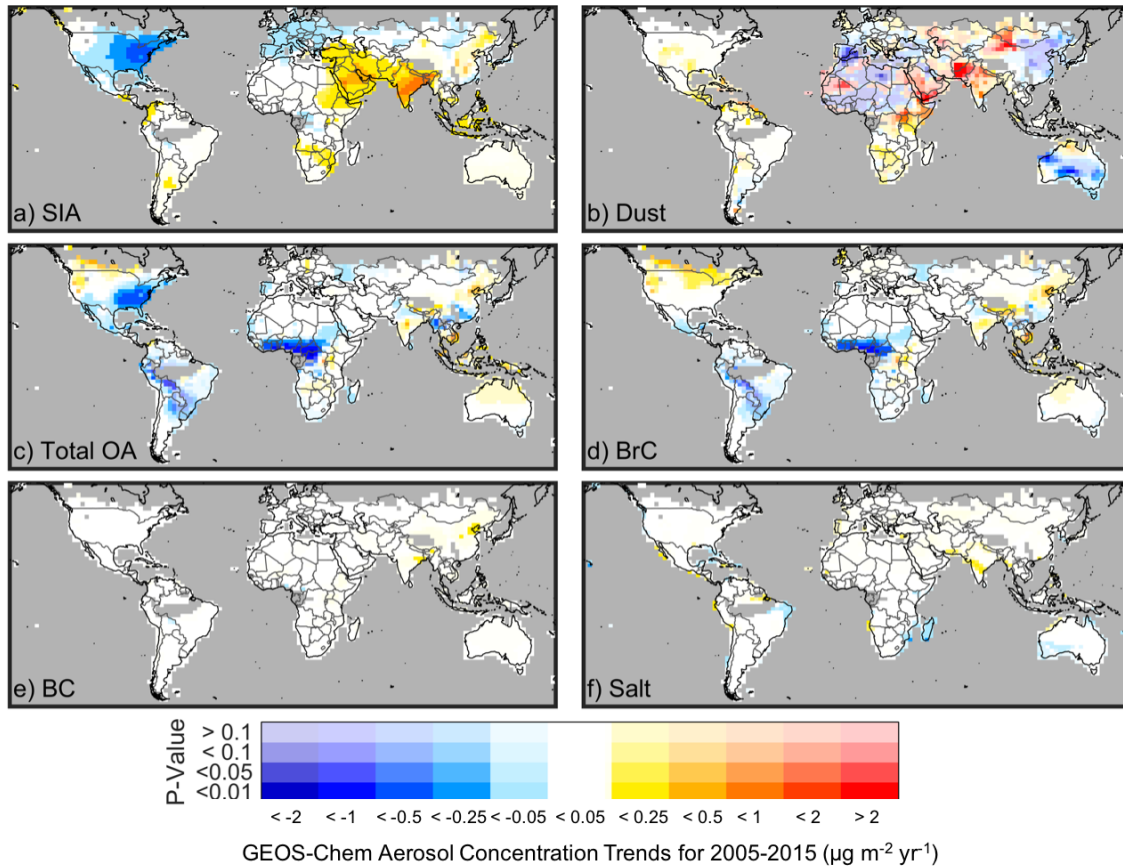

828

829 **Figure 5:** Seasonality of the trends in OMI UVAI values calculated from the Generalized Least
 830 Squares regression of monthly time series values over 2005-2015 for MAM (May, April, March),
 831 JJA (June, July August), SON (September, October, November), and DJF (December, January,
 832 February). The opacity of the colors indicates the statistical significance of the trend. Gray
 833 indicates persistent cloud fraction greater than 5%.

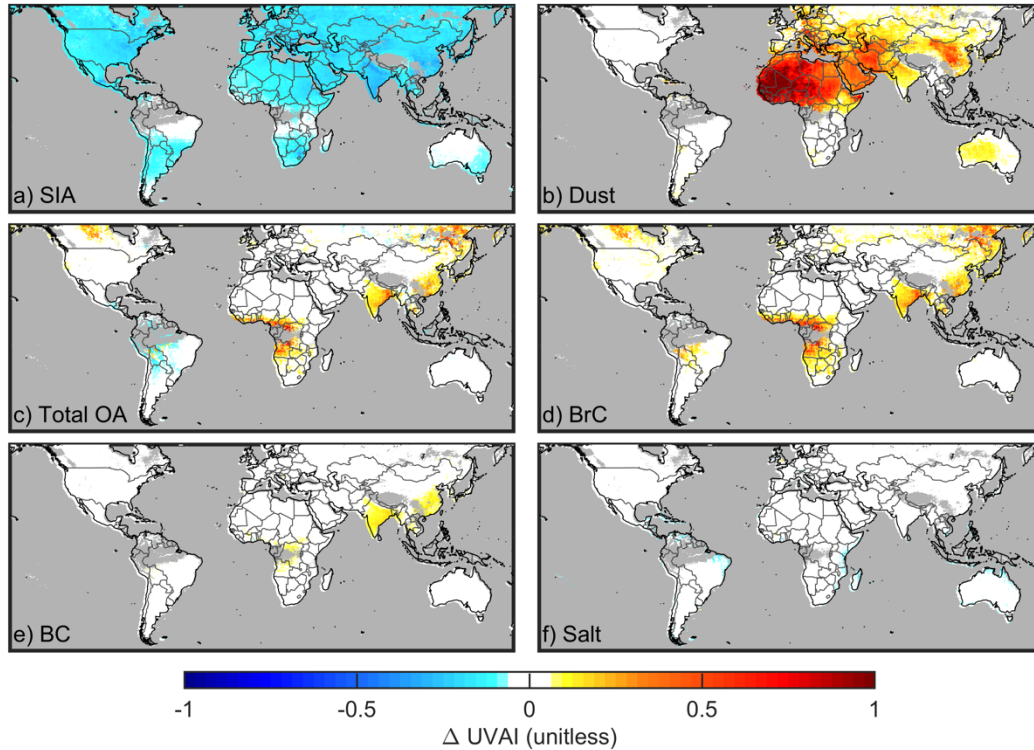

834

835 **Figure 6:** Seasonality of the trends in simulated UVAI values coincidentally sampled from OMI
 836 calculated from the Generalized Least Squares regression of monthly time series values over 2005-
 837 2015 for MAM (May, April, March), JJA (June, July August), SON (September, October,
 838 November), and DJF (December, January, February). The opacity of the colors indicates the
 839 statistical significance of the trend. Gray indicates persistent cloud fraction greater than 5%.

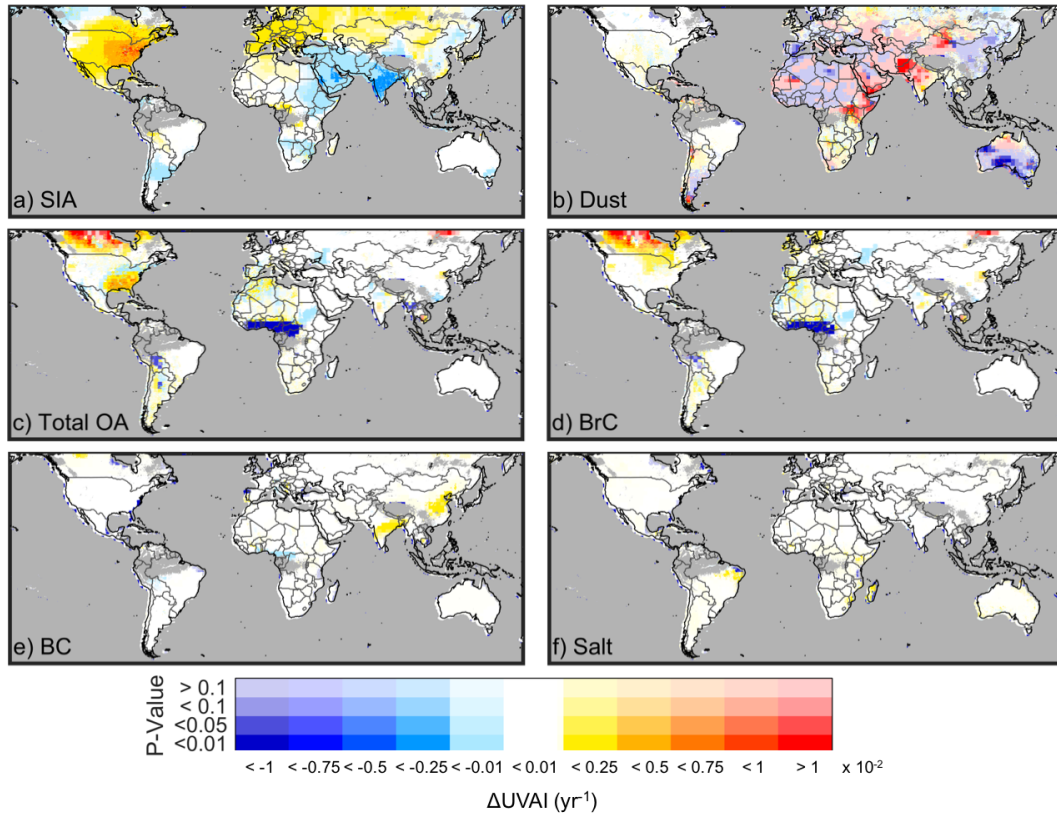

840

841 **Figure 7:** Trend in GEOS-Chem aerosol concentrations for a) secondary inorganic aerosol (SIA),
 842 b) dust, c) total organic aerosol (OA), d) brown carbon (BrC), e) black carbon (BC), and f) sea
 843 salt. The trends are calculated from the GLS regression of monthly aerosol concentration time
 844 series values over 2005-2015. The opacity of the colors indicates the statistical significance of the
 845 trend. Gray indicates persistent cloud fraction greater than 5%.

846

847 **Figure 8:** Annual mean change in simulated UVAI values for 2008 due to the doubling of
 848 concentrations of a) secondary inorganic aerosol (SIA), b) dust, c) total organic aerosol (OA), d)
 849 brown carbon (BrC), e) black carbon (BC), and f) sea salt from the GEOS-Chem simulation. Gray
 850 indicates persistent cloud fraction greater than 5%.

851

852 **Figure 9:** Change in simulated UVAI values due to the 2005-2015 trends in a) secondary inorganic
 853 aerosols (SIA), b) dust, c) total organic aerosol (OA), d) brown carbon (BrC), e) black carbon
 854 (BC), and f) sea salt from the GEOS-Chem simulation. Gray indicates persistent cloud fraction
 855 greater than 5%.
