

# ***Interactive comment on “Global evaluation and calibration of a passive air sampler for gaseous mercury” by David S. McLagan et al.***

## **Anonymous Referee #3**

Received and published: 22 February 2018

The present manuscript sounds as an extremely interesting study, useful for the scientific community involved in the global Hg monitoring in the atmosphere. Indeed this study accurately reports the results of a monitoring campaign comprising 20 sites worldwide, where active measurements of TGM (GEM+GOM) were performed simultaneously by validated analytical instruments.

A complete description of the PASs, as well as the sampling procedure and data analysis are reported, letting us to suppose that these easy-to-use devices can be a promising solution to implement the mercury monitoring network over the world.

On the other hand, a more precise and clear description about the Blanks PASs should be provided in order to better clarify the procedure of the "Blanks" exposure (reported within the Supplements), their composition and handling, time of exposure and the
