Abstract. Aerosol-cloud interaction is examined using ~~four-ten~~ years of data from the MODIS/Terra (morning orbit) and MODIS/Aqua (afternoon orbit) satellites. Aerosol optical depth (AOD) and cloud properties retrieved from both sensors are used to explore in a statistical sense the morning-to-afternoon variation of cloud properties in conditions with low and high AOD, over both land and ocean. ~~The results show that the morning to afternoon variation of cloud properties during the 3 hours between the Terra and Aqua overpasses have similar patterns (increase or decrease) over land under both low and high AOD conditions.~~ The results show that the interaction between aerosol particles and clouds is more complex and ~~of greater uncertainty over land than over ocean.~~ The variation in $d(\text{Cloud}_X)$, defined as the mean change in cloud property Cloud_X between the morning and afternoon overpasses in high AOD conditions minus that in low AOD conditions, is different over land and ocean. This applies to cloud droplet effective radius (CDR), cloud fraction (CF) and cloud top pressure (CTP), but not to cloud optical thickness (COT) and cloud liquid water path (CWP). ~~Both COT and CWP increase over land and ocean after the timestep, irrespective of the AOD. However, the initial AOD conditions can affect the amplitude of variation of COT and CWP.~~ The effects of initial cloud fraction and meteorological conditions on the change in CF ~~under low and high AOD conditions after the 3 hours timestep over land~~ are also explored. ~~There are two cases are considered: (1) when the cloud cover increases; (2) when the cloud cover decreases. From~~ For both ~~two~~ cases, we find that almost all the values of $d(\text{CF})$ are positive, indicating that the variations of CF are ~~larger in high AOD than that in low AOD after the 3 hours timestep. The results also showing that large increase of cloud fraction occurs when scenes experience large AOD and stronger upward motion of air parcels. Furthermore, the increase rate of cloud cover is larger for high AOD with increasing RH scenes with large cloud fraction experience large AOD and larger RH when RH is larger than 20%. We also find that smaller increase of cloud fraction occurs when scenes experience larger AOD and larger initial cloud cover. upward motion of air parcels can enhance the cloud cover much more when AOD is high than when it is low. In contrast, the increase of cloud cover of with increasing relative humidity is much stronger in a relatively clean atmosphere with low AOD than in a more polluted atmosphere. Meanwhile, stable atmospheric conditions favour the development of a low cloud cover, especially when AOD is high.~~ Overall, the analysis of the diurnal variation of cloud properties provides a better understanding of aerosol-cloud interaction over land and ocean.

Key words: MODIS, cloud development, aerosol-cloud interaction, urban clusters, ocean

1 **1 Introduction**

2 Clouds and cloud systems are crucial elements in the energy cycle of our planet (Hartmann et al., 1992;
3 Webb et al., 2006). Clouds affect the global energy budget by reflecting incoming solar radiation, and thus
4 cool the Earth surface, and by absorption and re-emitting outgoing terrestrial radiation which contributes to
5 warming of the surface. In addition to the radiative effects, clouds also influence the hydrological cycle of
6 the Earth through precipitation (Stephens et al., 2002). Due to interactions with aerosols, the climatic effects
7 of clouds are further complicated (Rosenfeld, 2000; Twomey, ~~2007~~1974; Twomey, 1977). Aerosols can
8 serve as cloud condensation nuclei (CCN), depending on their hygroscopic properties, and when activated
9 they can change the cloud microphysical properties. The increase of CCN, while the liquid water path
10 remains constant, usually results in more numerous cloud droplets with smaller cloud droplet radius (CDR)
11 due to the competition for the same amount of water vapour. Thus, cloud albedo increases and the smaller
12 cloud droplet effective radius [in most cases](#) results in the suppression of precipitation ~~in most cases~~, which
13 in turn results in a longer cloud lifetime, and maintaining a larger liquid water path (Albrecht, 1989;
14 Feingold et al., 2001). Therefore, it is important to understand the interaction between aerosols and clouds
15 and the effect of different processes on cloud development.

16 Numerous studies have shown that aerosol particles can affect cloud properties on regional and global scales
17 (Krüger and Graßl, 2002; Menon et al., 2008; Rosenfeld et al., 2014; Sporre et al., 2014; Saponaro et al.,
18 2017). Satellite measurements suggest that the cloud droplet effective radius (CDR) decreases with
19 increasing aerosol optical depth (AOD, which is used in this paper as a proxy for aerosol concentration),
20 which is consistent with Twomey's theory (Kaufman et al., 2005; Matheson et al., 2005; Meskhidze and
21 Nenes, 2010). However, other observational and model studies reported that CDR tends to increase with
22 aerosol loading in some study areas, especially over land (Feingold et al., 2001; Yuan et al., 2008; Grandey
23 and Stier, 2010; Liu et al., 2017). A different behaviour of cloud cover as a function of AOD for different
24 aerosol loadings (low or high) has been found by Kaufman and Koren (2006) and Koren et al. (2008).
25 However, the observed correlations between aerosol and cloud cannot be simply attributed to the effects of
26 aerosols on clouds alone since other factors such as variations in meteorological conditions could play a role
27 (Loeb and Schuster, 2008; Reutter et al., 2009; Koren et al., 2010; Su et al., 2010; Stathopoulos et al., 2017).
28 "Snapshot" studies, where the aerosol and cloud properties are retrieved at the same time, have the
29 advantage that they represent the total time-integrated effect of aerosols on cloud properties (Meskhidze et
30 al., 2009; Gryspeerdt et al., 2014). However, the use of "snapshot" correlations is limited to a single
31 overpass time and limits the ability to distinguish aerosol-cloud interactions from meteorological
32 covariation or retrieval errors (Gryspeerdt et al., 2014). Therefore, the history of meteorological forcing is
33 an important determinant of cloud state. Matsui et al. (2006) investigated the properties of low clouds
34 derived from semiglobal observations by the Tropical Rainfall Measurement Mission (TRMM) and
35 explored the correlations of these cloud properties with aerosols (as indicated by the aerosol index or AI)
36 and with lower-tropospheric stability (LTS) on a diurnal scale. They found that aerosols affect the CDR
37 stronger for low LTS than for high LTS. Mauger and Norris (2007) used MODIS/Terra data to examine the
38 evolution of marine boundary layer clouds over several days but they may have missed important effects
39 occurring on a sub-daily timescale. Meskhidze et al. (2009) investigated the evolution of cloud properties
40 between the MODIS/Terra and MODIS/Aqua overpasses as a function of MODIS/Terra AOD and found an

1 apparent increase in the breakup rate of stratocumulus clouds in high AOD environments. However, they
2 did not explain meteorological covariation that may generate spurious correlations.

3 Considering the complex aerosol composition and increasing aerosol trend during the last decades over
4 eastern China (Guo et al., 2011), a systematic assessment of the effect of aerosols on the properties of warm
5 clouds is ~~desperately~~ needed, over both land and ocean. In this paper, aerosol-cloud interaction is examined
6 using multi-year statistics of remotely sensed data from the two MODIS sensors aboard NASA's Terra
7 (daytime equator crossing time at 10:30 LT) and Aqua (daytime equator crossing time at 13:30 LT)
8 satellites. The retrieval of the AOD and cloud properties from both sensors allows us to explore the
9 morning-to-afternoon variation of cloud properties in conditions with either low or high AOD, over land and
10 over ocean, and for different climate regimes. This variety of conditions allows us to identify similarities
11 and differences in the effects of aerosols on clouds and thus better understand aerosol-cloud interaction. We
12 also explore the effect of meteorological history on the interaction between aerosols and clouds. ~~In this~~
13 ~~paper, w~~We focus on low-level water clouds. The paper is organized as follows. The data and region of
14 interest are described in Section 2. The main methodology is introduced in ~~section-Section~~ 3. The results and
15 analysis are presented in ~~section-Section~~ 4. Overall conclusions and potential future improvements are
16 discussed in ~~section-Section~~ 5.

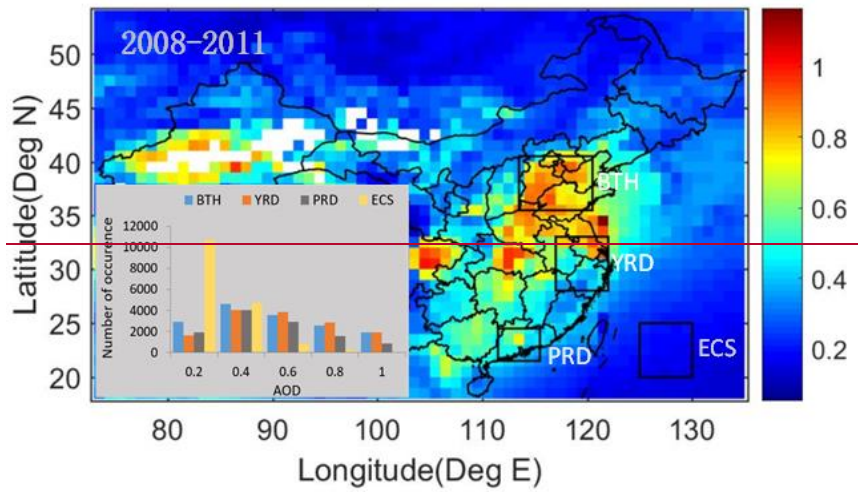

17 2 Approach

18 2.1 Study area

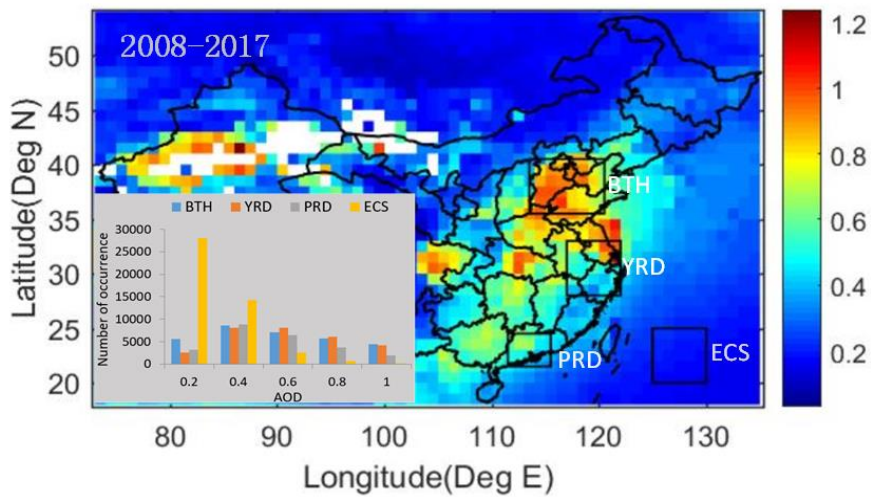

19 Aerosol concentrations in Eastern China are very high due to both direct emissions and secondary aerosol
20 formation from precursor gases such as NO₂, SO₂ and VOCs. They are produced by anthropogenic activities
21 such as industry, transportation and heating, black carbon and other carbonaceous aerosols produced by
22 biomass burning, dust aerosols produced from the deserts, etc. Aerosol particles influence the local climate
23 such as monsoon intensity and the distribution of precipitation. ~~conversely, monsoon in~~ In eastern China, the
24 monsoon in turn ~~also~~ plays an important role in the wet deposition and transport of aerosol particles (Li et al.,
25 2016). The Asian monsoon system plays an important role in the precipitation across the country (Kourtidis
26 et al., 2015). In early April, the pre-monsoonal rain period starts over southern China and the summer
27 monsoon rain belt moves northward to the Yangtze River basin in June. Further, the rain belt arrives in
28 northern China in July and the monsoon rain belt propagates back to southern China in August. The length
29 of the rain season differs between southern and northern China with the migration of the monsoon across
30 China (Song et al., 2011). Based on these characteristics, four regions with different aerosol emission levels
31 and climate characteristics were selected to study the indirect effects of aerosol particles on cloud micro-
32 and macro-physical properties. The Beijing-Tianjin-Hebei (BTH), Yangtze River Delta (YRD) and Pearl
33 River Delta (PRD) urban clusters are characterized as a temperate monsoon climate region, a subtropical
34 monsoon climate region, and a tropical monsoon climate region, respectively. The BTH domain
35 (35.5°N-40.5°N, 113.5°E-120.5°E) is an area with high AOD levels due to rapid industrial and economic
36 development (Fig. 1). The YRD domain (28°N-33°N, 117°E-122°E) is a major source region of black
37 carbon (Streets et al., 2001; Bond et al., 2004) and sulfate (Lu et al., 2010). The PRD domain
38 (21.5°N-24.5°N, 111.5°E-115.5°E) is an area within the intertropical convergence zone (ITCZ) migration

1 belt, with high anthropogenic aerosol emissions (Streets et al., 2003; Streets et al., 2008; Lei et al., 2011). In
2 addition, one domain (20°N-25°N and 125°E-130°E), which is located in the Eastern China Sea (ECS for
3 short), has been selected as study area for comparison. The ECS domain is relatively clean, but [it is](#) often
4 impacted by aerosol particles transported from the highly industrialized eastern China (Wang et al., 2014).
5 The study period is [104](#) years, i.e. 2008-~~2011~~[2017](#).

6 The location of the four clusters (three urban and one ocean) studied here (Beijing-Tianjin-Hebei: BTH, Yangtze
7 River Delta: YRD, Pearl River Delta: PRD and Eastern China Sea: ECS) are marked with black rectangles. The inset
8 shows a histogram for the occurrence of AOD values in each of the four clusters during the period 2008-~~2011~~2017.

9 2.2 Data used

10 The aerosol and cloud properties used in this study were derived from the MODIS instruments on the
11 Terra and Aqua satellites. Since these instruments are of the same design, errors due to instrument
12 differences are minimal although some differences have been reported due to degradation of
13 MODIS/Terra (Xiong et al., 2008; Levy et al., 2010; Xiong et al., 2008). The MODIS L3 collection
14 ~~5-16.1~~ data (which was downloaded from <https://ladsweb.modaps.eosdis.nasa.gov/>) provides daily
15 aerosol and cloud parameters on a 1° by 1° spatial grid. The time difference between the Terra and Aqua
16 overpasses is about three hours, with variations due to swath width. In the following, the time difference
17 between the MODIS/Terra and Aqua observations is referred to as the timestep. The application of daily
18 MODIS satellite data on a 1° by 1° spatial grid in this study on aerosol-cloud interaction (ACI) ensures
19 that the aerosol and cloud retrievals are coincident. The MODIS instruments have 36 spectral bands, the
20 first seven of these (0.47- 2.13 μm) are used for the retrieval of aerosol properties (Remer et al., 2005)

1 while cloud properties are retrieved using additional wavelengths in other parts of the spectrum (Platnick
2 et al., 2003). More detailed information on algorithms for the retrieval of aerosol and cloud properties is
3 provided at <http://modis-atmos.gsfc.nasa.gov>. In this study on ACI we use the AOD at 550 nm (referred
4 to as AOD throughout this manuscript), CDR, cloud liquid water path (CWP), cloud optical thickness
5 (COT), cloud fraction (CF), cloud top pressure (CTP) and cloud top temperature (CTT) from both
6 instruments. AOD is used as a proxy for the amount of aerosol particles in the atmospheric column to
7 investigate ACI (Andreae, 2009; Kourtidis et al., 2015). To reduce a possible over-estimation of the
8 AOD, cases with AOD greater than 0.8 were excluded from further analysis. The focus of this study is on
9 warm clouds with CTP ~~greater-larger~~ than 700 hPa, CTT ~~greater-larger~~ than 273K and CWP lower than
10 200 g m⁻², as most aerosols exist in the lower troposphere (Michibata et al., 2014).

11 In addition, to explore the effect of meteorological conditions on ACI, we use the daily temperature at the
12 1000 hPa and 700 hPa levels, relative humidity at the 750hPa level and pressure vertical velocity (PVV)
13 at the 750 hPa level. LTS is defined as the difference in potential temperature between the free
14 troposphere (700hpa) and the surface, which can be regarded as a measure of the strength of the inversion
15 that caps the planetary boundary layer is representative of typical thermodynamic conditions (Klein and
16 Hartmann, 1993; Wood and Bretherton, 2006). These meteorological data were obtained from daily
17 ERA Interim Reanalysis data which contains global meteorological conditions on a grid of 1°×1° with 37
18 levels in the vertical (1000-1 hPa) every six hours (00:00, 06:00, 12:00, 18:00 UTC)
19 (<http://apps.ecmwf.int/datasets/data/interim-full-daily/>). The meteorological properties were resampled
20 to 10:30 (local time) by taking a weighted average of the properties at the two closest times (00:00 UTC
21 and 06:00 UTC) provided by ERA Interim.

22 In this study, high and low AOD are defined as the highest and lowest quartile for each 1°×1° location to
23 reduce climatological spatial gradients in aerosol and cloud parameters. As a result, the difference
24 between high and low AOD varies by location. So, for each 1° x 1° grid cell, ~~1457-3642~~ data samples are
25 available for the 104-year study period.

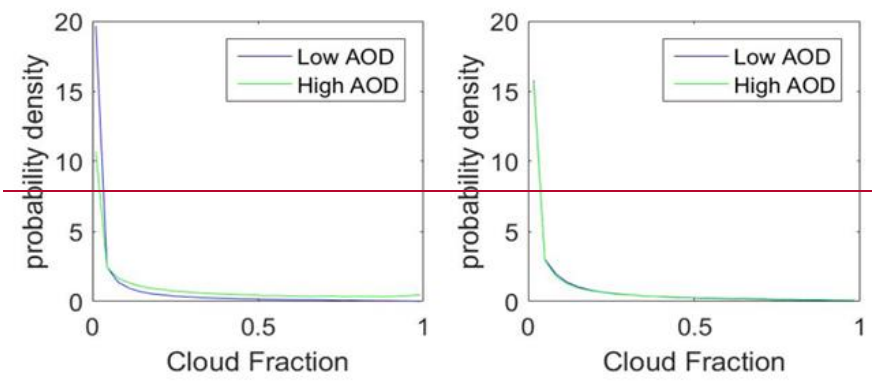

26 **3 Method**

27 **3.1 Normalization for initial background**

28 For the comparison of the difference in cloud properties in high and in low AOD conditions and the
29 change in this difference during the time step, we need to ensure that the initial conditions are similar, i.e.
30 the probability distributions of a cloud parameter Cloud_X at the start of the time step for the low and
31 high AOD cases should be similar. Any change in this distribution at the end of the time step can then be
32 attributed to changes in cloud properties due to aerosol and/or meteorological effects. To reduce the
33 difference between the initial probability distribution of Cloud_X in high and low AOD conditions at the
34 start of the timestep, normalized histograms of cloud properties and meteorological parameters are made
35 for high and low AOD conditions following the method described by Gryspeerdt et al. (2014).

36 ~~It is necessary to reduce possible non-aerosol effects linking cloud properties and AOD at the start time~~
37 ~~to reveal the strong link between cloud properties and AOD.~~ In Fig. 2 we illustrate the process to remove

1 possible effects linking, as an example, CF and AOD. Normalized histograms of CF are made for the
 2 high and low AOD conditions following Gryspeerdt et al. (2014) with the difference that in the current
 3 study AOD is used instead of AI (Andreae, 2009; Kourtidis, et al., 2015). The CF probability density
 4 functions for low and high AOD conditions at the start time are different as illustrated ~~for CF~~ in Fig. 2a.
 5 This difference indicates a link between CF and AOD at the start of the time step which needs to be
 6 removed to detect the effect of changes during the time step. This is achieved, following the process
 7 described in more detail by Gryspeerdt et al. (2014). In brief, for each bin data points are drawn out
 8 randomly from the conditions with the larger probability density frequency until both distributions match.
 9 This is performed independently for each bin and the entire process is repeated until the ~~conditions have~~
 10 ~~sufficiently similar~~ normalised histograms ~~in both AOD conditions are similar~~. ~~As a result of this~~
 11 ~~normalization process, the~~ ~~After that, both conditions have almost the same~~ CF distributions ~~at the start~~
 12 ~~of the timestep~~ ~~are nearly identical for both AOD condition~~ ~~through the normalization process, i.e.~~
 13 ~~indicating that~~ the non-aerosol effect linking CF and AOD has been removed. This technique has also
 14 been applied to ensure that the high and low AOD conditions have the same probability distributions ~~of~~
 15 ~~for~~ CDR, COT, CWP and CTP at the start time. ~~Among those cloud properties, this process of ,even~~
 16 ~~though we know that the normalization for the cloud fraction has the greatest effect on the cloud fraction~~
 17 ~~and it's dependence on~~ ~~on the relationship between aerosol and cloud interaction among those cloud~~
 18 ~~properties even though we find that the normalization for the cloud fraction made the biggest difference~~
 19 ~~by far. In the further analysis~~ ~~Throughout the work~~, we only take a subset of original data by removing
 20 random samples until the histograms are similar.
 21 ~~Note that here and in the following sections, normalised histograms of cloud properties are made for the~~
 22 ~~high and low AOD populations based are made on for the whole region (Section 3.1), because as there is~~
 23 ~~relatively small the data volume based on each 1° x 1° location is relatively small. However, the~~
 24 ~~difference between of the cloud properties between for the low and high AOD at the start time is based on~~
 25 ~~each 1° x 1° location (Section 4.1). So the difference of the cloud properties between the low and high~~
 26 ~~AOD at the start time is not zero.~~

27

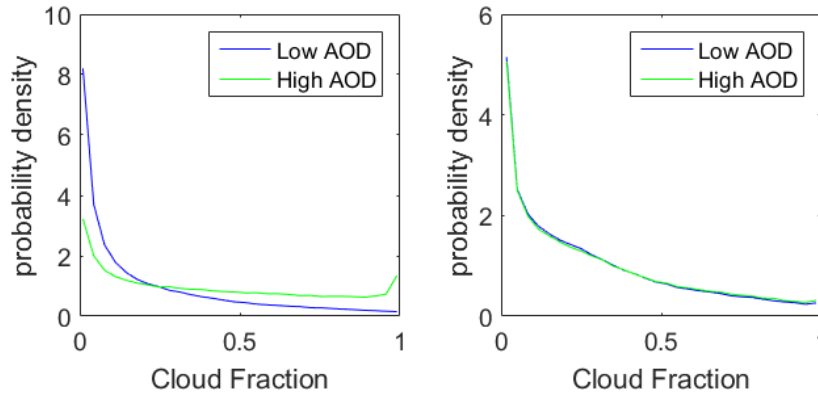

Figure 2 An example of the probability density distribution of warm cloud fraction (CF) for low and high AOD conditions. (a) there is a strong link between AOD and CF before histogram normalization, (b) the link is reduced after histogram normalization.

3.2 The definition of $d(\text{Cloud}_X)$

After removal of the potential relationships between AOD and cloud parameters at the time of the Terra (morning) overpass, as described in Sect. 3.1, effects of aerosol particles on cloud properties are investigated from the recovery change inef the relationship between AOD and cloud parameters over the timestep. For cloud property Cloud_X (where $X = \text{CF}, \text{COT}, \text{CWP}, \text{CDR}$ or CTP), the change during the timestep is indicated by ΔCloud_X . The mean ΔCloud_X for high AOD is then indicated by $\overline{\Delta\text{Cloud}_X[\text{High AOD}]}$ ~~$\Delta\text{Cloud}_X[\text{High AOD}]$~~ and similar for low AOD. The difference between the mean change in Cloud_X during the timestep in high and low AOD conditions is then indicated by $d(\text{Cloud}_X)$:

$$d(\text{Cloud}_X) = \overline{\Delta\text{Cloud}_X[\text{High AOD}]} - \overline{\Delta\text{Cloud}_X[\text{Low AOD}]}$$

~~For example, $d(\text{CWP})$ would be the difference between the mean change in CWP in high AOD conditions minus that in low AOD conditions.~~

The high AOD is representative of polluted atmospheric conditions, and the low AOD is representative of clean atmospheric conditions. The difference ($d(\text{Cloud}_X)$) between the mean values of the cloud property Cloud_X during clean (low AOD) and polluted (high AOD) conditions indicates the effect of these two aerosol cases on the cloud property Cloud_X . For example, $d(\text{CWP})$ would be the difference between the mean change in CWP in high AOD conditions minus that in low AOD conditions.

Student's t test is used to determine whether two data sets ~~of data~~ are significantly different from each other. The marker ** at the top right corner of symbol "+" (or "-") denotes that the difference between a change in cloud property and zero is significant (at 95% confidence level).

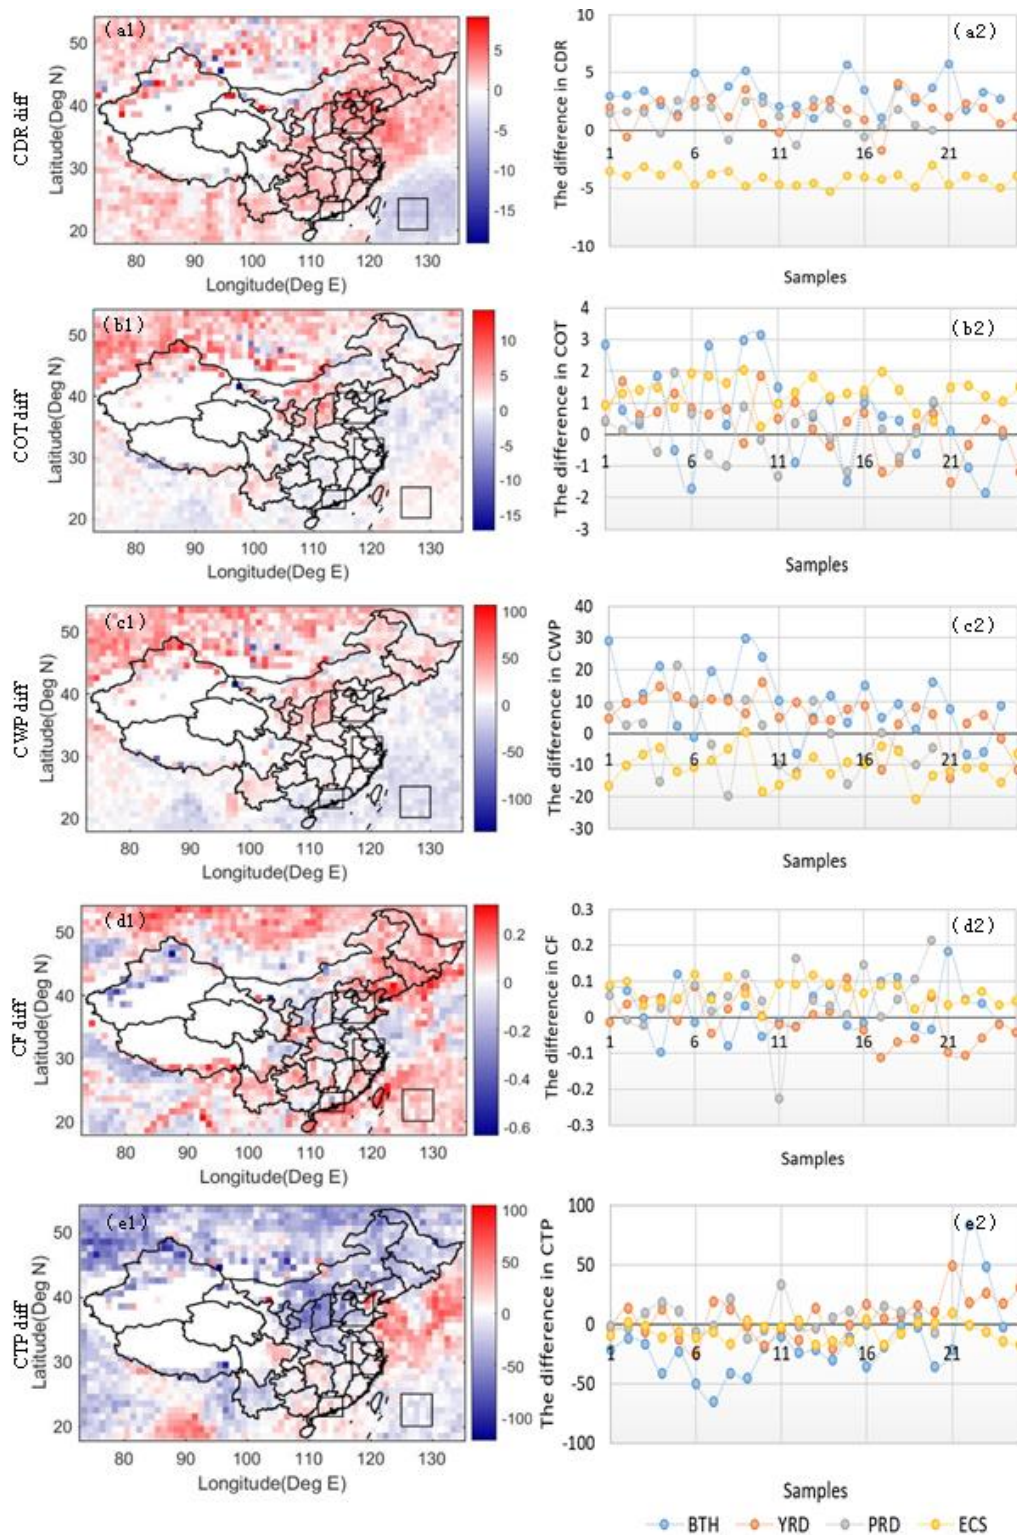

4 Results and Discussions

4.1 The difference of cloud properties between the low and high AOD at the start time

The difference in the mean cloud properties (CDR, CF, COT, CWP and CTP) during high and low AOD

1 conditions at the start time for each $1^\circ \times 1^\circ$ grid cell, i.e.,
 2 $\left\{ \overline{\text{Cloud_X[High AOD]} - \text{Cloud_X[Low AOD]}} \right\}_{t=0}$ represents the change in cloud properties due to the
 3 higher AOD. Figure 3 shows the spatial distributions of these differences (left column) and sample series
 4 of the difference (right column) for the four regions of interest (right column). The selection of samples for
 5 each region is according to the pixels in the region. ~~There are large variations in the response of the cloud~~
 6 ~~parameters to the higher AOD in the four regions.~~ Figures 3(a1-a2) show that over the ECS, CDR is
 7 smaller at high AOD than at low AOD, which is consistent with Twomey's effect. In contrast, over the
 8 ~~BTH and the YRD~~ three urban clusters, CDR is larger at high AOD. This behavior has been observed
 9 before for warm clouds in conditions with high AOD (Liu et al., 2017) and may result from the intense
 10 competition for the available water vapour and the evaporation of smaller droplets as a consequence of the
 11 high aerosol abundance over these regions (Yuan et al., 2008; Tang et al., 2014; Wang et al., 2014; Liu et
 12 al., 2017). ~~However, over the PRD urban cluster no statistically significant difference in CDR is observed~~
 13 ~~between high and low AOD.~~ For COT (figures 3(b1-b2)) the values are significantly higher at high AOD
 14 over the ECS and the BTH, however, COT does not show a significant difference between the situations
 15 at low and high AOD over the YRD and PRD. These results indicate that there is no clear dependence of
 16 COT on aerosol load, and also the aerosol type may influence the aerosol effect on COT. ~~and the PRD,~~
 17 ~~in contrast to the smaller value observed over the BTH and the YRD urban clusters. Likely, this is due to~~
 18 ~~the radiative effect and possible retrieval artefacts as explained in Liu et al. (2017). They inferred that the~~
 19 ~~evaporation of cloud droplets caused by locally absorbing aerosol makes clouds thinner and the presence~~
 20 ~~of absorbing aerosol may reduce the satellite retrieved COT.~~ Figures 3(c1-c2) shows that CWP is lower at
 21 high AOD over the ECS, which is in clear contrast with the so-called "lifetime effect" proposed by
 22 Albrecht in 1989 not in agreement with COT variation. In contrast, over the BTHPRD, CWP behaves
 23 similar to COT and is higher at high AOD. Furthermore, CWP is also higher at high AOD. Ackerman et
 24 al. (2004) reported that CWP is not generally observed larger, but significantly smaller in high AOD
 25 conditions. They reported that CWP response to the increasing AOD is determined by the balance of two
 26 competitive factors: moistening from precipitation decrease and drying from increasing entrainment of
 27 dry overlaying air. ~~However, over the BTH and the YRD urban clusters CWP does not show a significant~~
 28 ~~difference between the situations at low and high AOD. Over the ECS, the change in CF between low and~~
 29 ~~high AOD is similar to that of CTP (Figs. 3(d1-d2, e1-e2)): both parameters are larger at high than at low~~
 30 ~~AOD over that area.~~ With increasing AOD, CF does not show any significant correlation between
 31 changes in AOD and CDR variations over the BTH and YRD. However, CF is larger at high AOD over
 32 the PRD and ECS. Wang et al., (2014) also found that when aerosol loading is relatively small, cloud
 33 cover is found to increase over the YRD and ECS in response to aerosol enhancement regardless of RH
 34 conditions. Meanwhile, over the YRD urban cluster CF is lower and CTP is higher at high AOD, as
 35 suggested by Liu et al. (2017). In contrast, CTP is lower at high AOD over the BTH and ECS. Many
 36 studies have also reported that with higher cloud altitude CTP decreases ~~ed~~ in most of the places as AOD
 37 increases ~~ed~~ except for some regions at low AOD (Myhre et al., 2007; Kaufman et al., 2005 and Alam et al.,
 38 2010). This might have resulted from the suppression of the precipitation by increasing cloud lifetime
 39 and thus also affecting the cloud albedo and changing the cloud top pressure. ~~and the PRD urban clusters~~
 40 CF is higher and CTP is lower at high AOD. Overall, it looks like the aerosol-cloud interactions behave

1 quite similar, over the BTH and YRD urban clusters, both of which have high pollution levels, while over
2 the PRD they show the opposite behavior. The difference in the response of the cloud parameters to low
3 and high aerosol conditions over the four regions may be caused by the difference in pollution levels or
4 pollution types including black carbon, sulphate, sea spray, etc.

2 Figure 3 Spatial distribution of the differences in cloud properties (top to bottom: CDR, COT, CWP, CF and CTP)
 3 between the highest and the lowest MODIS AOD quartiles (highest - lowest) at the start time of the timestep
 4 (MODIS/Terra) (left, a1-e1) and sample series of the differences in cloud properties (CDR, COT, CWP, CF and CTP)
 5 between the highest and the lowest MODIS AOD quartiles (highest - lowest) at the start time of the timestep
 6 (MODIS/Terra) (right, a2-e2) over Eastern China for the time period 2008-2014+2017. [See legend at the bottom for the](#)
 7 [meaning of the colours identifying the different regions.](#)

8 To better characterize the variation in cloud properties between high and low AOD, Table 1 summarizes [the](#)
 9 [difference of in cloud properties between high and low AOD at start time](#) [the responses of cloud properties to](#)
 10 [the increasing AOD at the start time](#) for the four study areas. We find that different regions with various

aerosol emission levels and different climate characteristics show different ACI patterns. Some links between aerosol and cloud in the four regions are different from those of previous studies over China (Wang et al., 2014; Tang et al., 2014; Kourtidis et al., 2015; Liu et al., 2017), which might be due to the use of different data sets (MODIS C6.1 versus older versions), hypothesis and target areas characterized by complex aerosol compositions and varying meteorological conditions. Over the ECS region, CDR and CWP in high AOD conditions are smaller than at low AOD, but COT, CF and CTP are higher. Over the BTH urban cluster, the higher AOD results in higher CDR and CF, while COT and CTP are smaller. Over the YRD urban cluster, CDR and CTP are larger, but COT and CF are smaller at high AOD. Over the PRD urban cluster, COT, CWP and CF are larger, but CTP is smaller at high AOD. Overall, the result implies that the interaction between aerosol particles and clouds is more complex and less predictable of greater uncertainty over land (BTH, YRD and PRD) than over ocean (ECS). Jin and Shepherd (2008) also noted that aerosols affect clouds more significantly over ocean than over land. They suggested that dynamic processes related to factors like urban land cover may play at least an equally critical role in cloud formation.

PRD	±	+**	±	-	+**	+**
ECS	±	-**	+**	-**	+**	-**

Note: '+' indicates increasing, '-' indicates decreasing and '**' at the top right corner of the symbol "+" (or "-") denotes that the difference between a change in cloud property and zero is significant (at 95% confidence level).

Parameters	AOD	CDR	COT	CWP	CF	CTP
BTH	+	+	-	-	+	-
YRD	+	+	-	-	-	+
PRD	+	-	+	+	+	-
ECS	+	-	+	-	+	+

Note: '+' indicates increasing, '-' indicates decreasing and '-' indicates the response of cloud properties to the increasing AOD is not significant.

4.2 The meteorology of the four target regions

The meteorological and aerosol effects on clouds are reported to be so tightly connected at the same time, so and this connection must be accounted for in any study into aerosol-cloud interactions (Stevens and Feingold, 2009; Koren et al., 2010a). Even Although normalized histograms of meteorological parameters are made for high and low AOD conditions at the start time, but it is the normalization described in Sect. 3.1 is based on the whole region. So the Differences in meteorological conditions may still exist occur between each 1° by 1° grid cell. In this study, we analyze the meteorology of the different regions, helping in support of the interpretation of the regional variation of the relationships between aerosols and clouds.

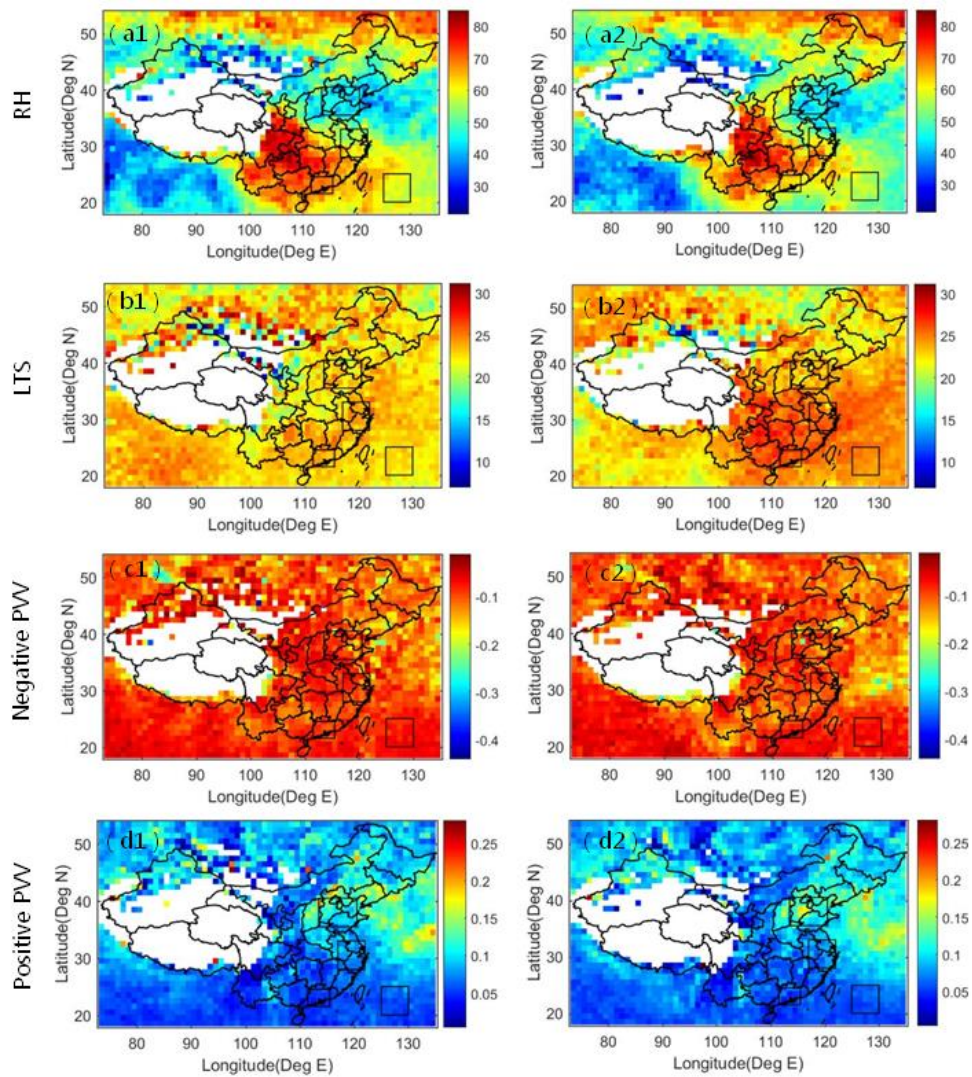

Figure 4 Spatial distributions of meteorological parameters (top to bottom: RH, LTS, positive PVV and negative PVV) at the start time of the timestep (MODIS/Terra) for low AOD conditions (left, a1-d1) and for high AOD conditions (right, a2-d2). All the data are averaged over all years between 2008 and 2017.

The spatial variations of the aerosol and cloud properties over the four regions, averaged over the years 2008-2017, are shown in Fig. 4. Over the urban clusters, we can see an increasing north-south pattern in RH and LTS, with the lowest values found in the PRD. For the negative PVV, the spatial distributions for the low and high AOD situations of the PVV are remarkably similar to each other, with the highest values over the BTH and decreasing toward the south to near zero over the PRD. However, in contrast, for the positive PVV, the PVV is low smallest over the BTH, with little variation over the study area. Overall, the spatial distribution of meteorological parameters over the YRD and PRD are similar to those over the ECS, irrespective of the AOD. Furthermore, the LTS is significantly larger in the high AOD conditions for all the four regions. Zhao et al. (2006) proposed that the enhancement in the atmospheric stability tends to depress upward motion and precipitation, leading to an increase in aerosol particles. The spatial distributions of both positive and negative PVV in the low AOD conditions are similar to those in the high AOD conditions.

4.3.2 The mean change in cloud properties over the timestep for low and high AOD

The differences between the mean afternoon and morning values of cloud properties in each $1^\circ \times 1^\circ$ grid cell in

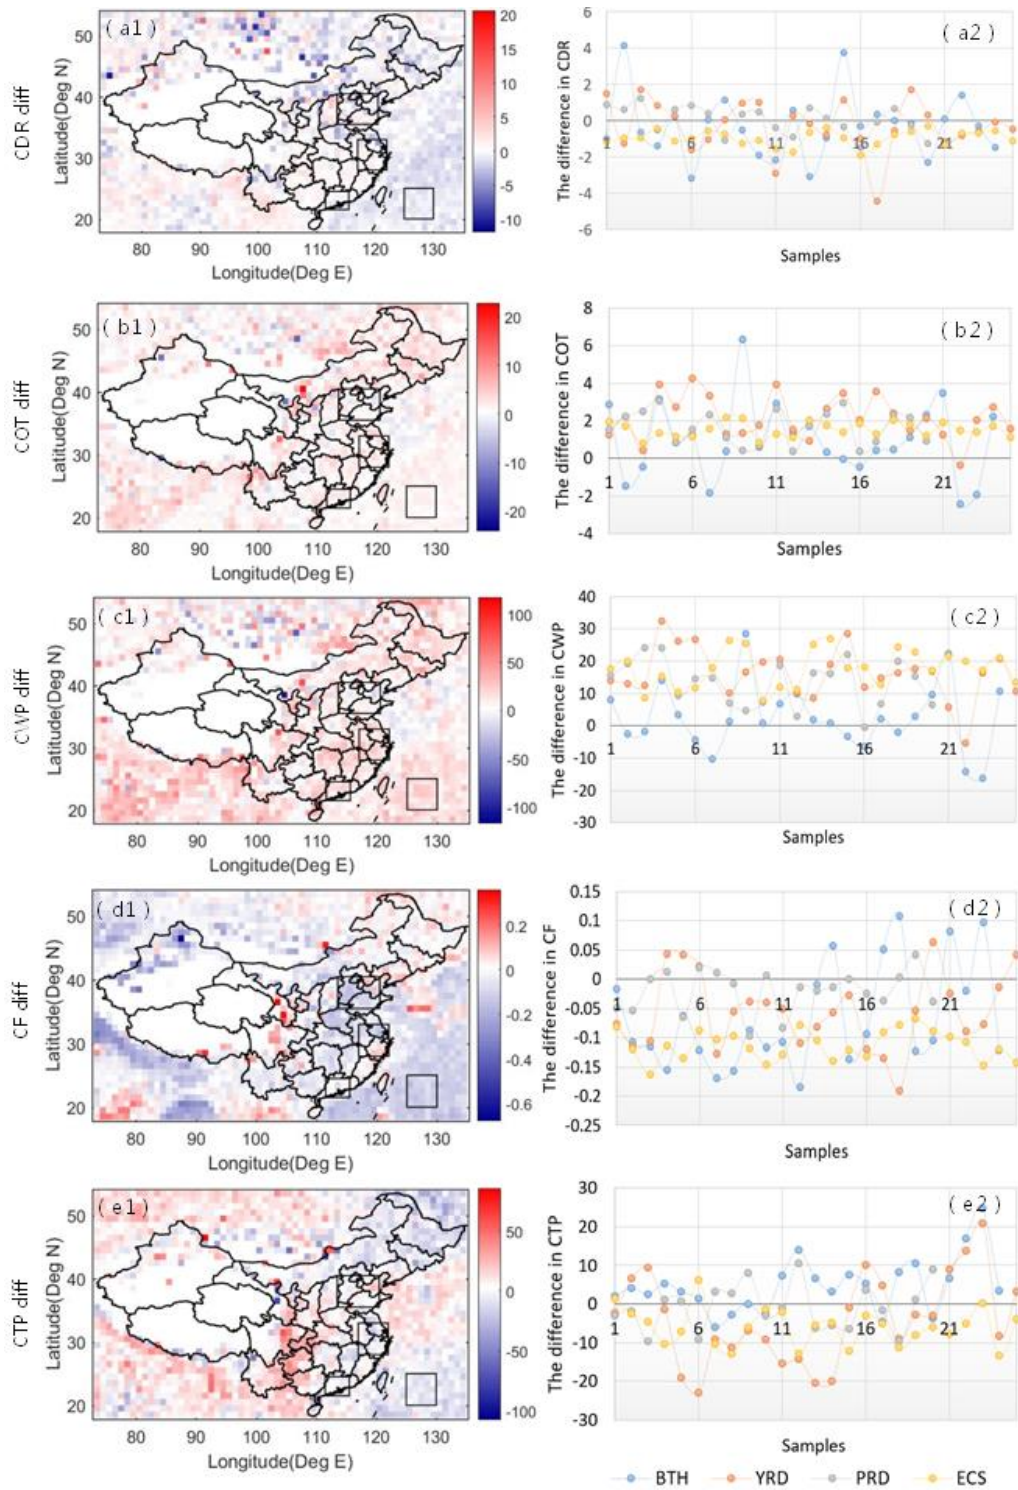

1 either low or high AOD conditions ~~in each $1^{\circ} \times 1^{\circ}$ grid cell minus those in the morning for low/high AOD~~
2 shows the variation of cloud properties during 3 hours of cloud evolution at low/high aerosol
3 concentrations. Figure 4-5 presents the spatial distributions (left, a1-e1) and the sample series (right, a2-e2)
4 of differences in cloud properties (CDR, COT, CWP, CF and CTP) after this 3-hour period for the lowest
5 MODIS/Terra AOD quartiles. Figure 65 shows the spatial distributions (left, a1-e1) and sample series (right,
6 a2-e2) of these differences for the highest MODIS/Terra AOD quartiles.

7 Overall, we look at statistics for a large dataset of 104 years. Concerning the effect of aerosol loading on
8 cloud parameters in each urban cluster, ~~a decrease of CF occurs over the BTH for low AOD conditions,~~
9 ~~which is opposite to the CTP variation for both two AOD conditions, none of the cloud parameters show a~~
10 ~~significant increase or decrease over the BTH under either low AOD or high AOD conditions, respectively.~~
11 For the variations of CDR ~~and CF~~ over the YRD urban cluster, a significant increase occurs ~~under high~~
12 ~~AOD conditions, which may be attributed to the higher RH (see figure 4(a1, a2)). And fAs regards~~ ~~the~~
13 ~~variation of CF and CTP, a significant decrease occurs under low AOD conditions, but for the variation of~~
14 ~~CTP, a significant decrease occurs over the YRD for both low and high AOD conditions. By contrast~~
15 ~~Likewise, an increases of the CDR, COT and CWP were was observed for both low and high AOD~~
16 ~~conditions over the PRD urban cluster, which is statistically significant. Furthermore, decreases of CF and~~
17 ~~CTP were observed for low AOD conditions and increases of CF and CTP were observed for high AOD~~
18 ~~conditions. From the perspective of considering all urban clusters (BTH, YRD and PRD), both COT and~~
19 ~~CWP all studied cloud properties (CDR, COT, CWP and CF) increase except CTP over land after during the~~
20 ~~3 hours timestep, which decreases during the timestep, for both low and high AOD (see red samples plot in~~
21 ~~Figures 4 and 5). Overall, the variation in cloud properties after the timestep over BTH is less significant~~
22 ~~than those over the YRD and PRD for both low and high AOD conditions after the timestep. This may~~
23 ~~result from leastss humid and morest unstable atmospheric environments over the BTH than over the other~~
24 ~~two among the three urban clusters (as shown in Section 4.2).~~

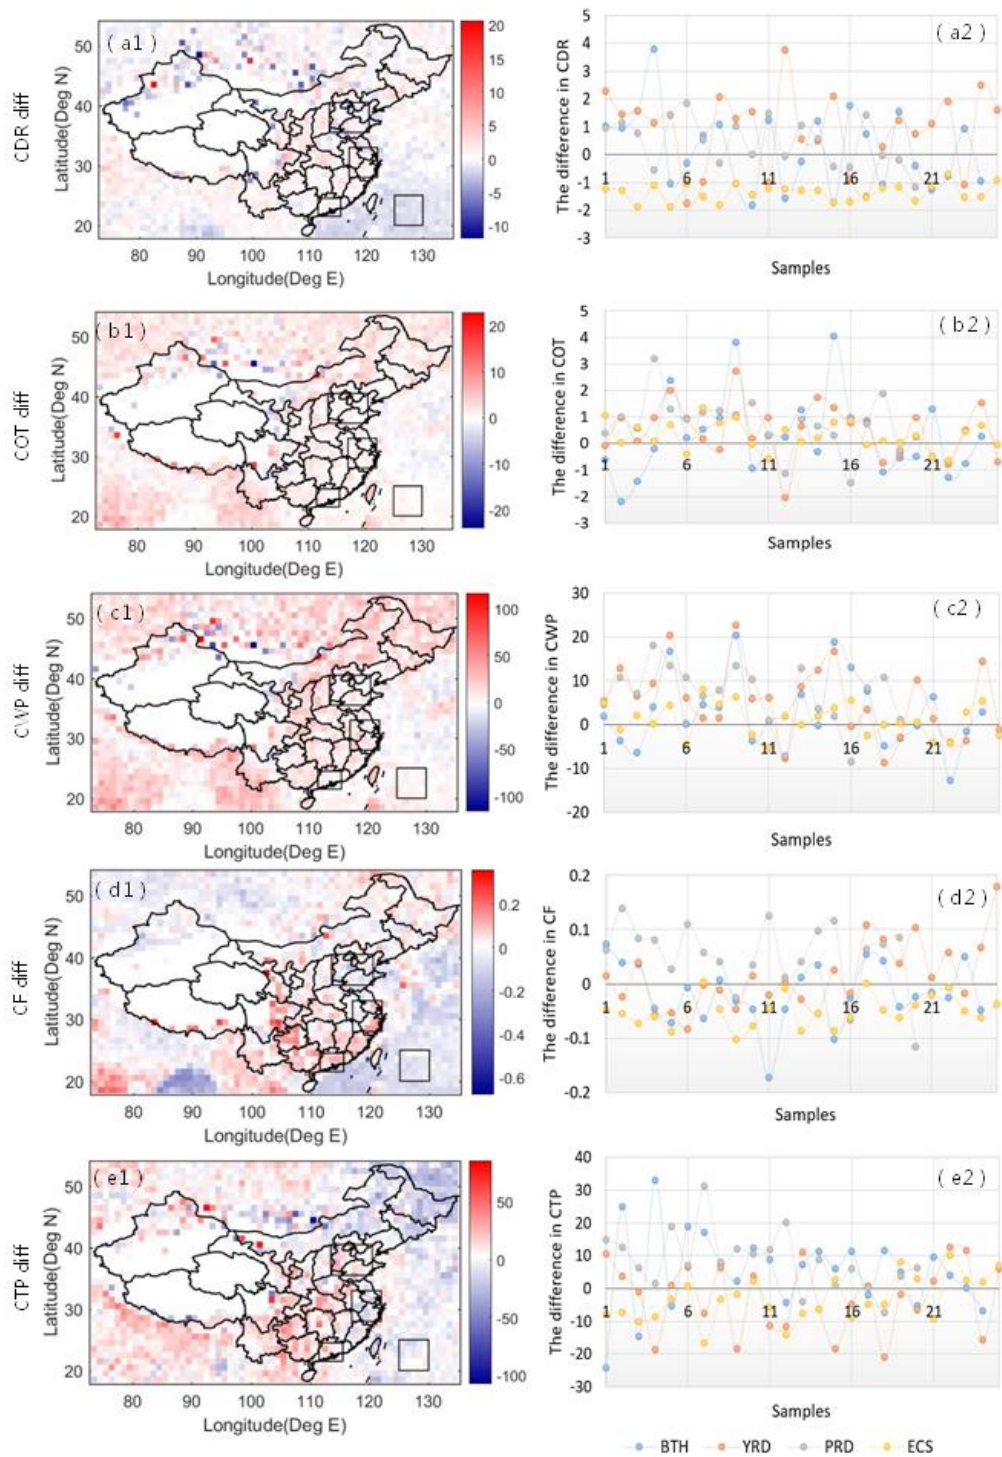

25 Over the ECS, in ~~both low and high~~ AOD conditions, CDR, ~~CF and CTP~~ decreases during the timestep
26 while COT and CWP increase (see Figure 45). ~~For high AOD conditions, the variations of the cloud~~
27 ~~properties (CDR, COT and CWP) during the timestep are similar to those for low AOD conditions (Figure~~
28 ~~5). Furthermore, it appears that COT and CWP increase more at low AOD than at high AOD. Having a~~
29 ~~closer look at the CF/CTP variation in both low and high conditions over ocean, we can find that CF~~
30 ~~decreases (CTP increases) in low AOD conditions and CF increases (CTP decreases) in high AOD~~
31 ~~conditions over ocean, albeit not over ECS.~~

32 In general, the variations ~~over 3 hours in COT and CWP in cloud properties~~ over land are similar to those
33 over ocean for both low and high AOD conditions ~~over 3 hours. Another significant similarity is that CF~~
34 ~~decreases for low AOD conditions over land and ocean after during the 3h timestep. Having a closer look at~~
35 ~~the CF variation over the YRD and PRD, we can findsee that CF increases in high AOD conditions~~
36 ~~after during the 3h timestep. It infersThis implies that the variation amplitude of CF may depend on the~~
37 ~~initial AOD conditions. The decrease in afternoon cloud cover over ocean confirms that the largest cover~~
38 ~~for marine clouds is reached early in the morning as was also concluded by (Meskhidze et al., (2009). Two~~
39 ~~significant differences are found between land and ocean areas. Meanwhile, oneOnea significant difference~~
40 ~~is found between land and ocean areas, that is, i.e. -in high AOD conditions CDR increases over land but~~
41 ~~decreases over ocean after during the 3h timestep under high AOD conditions, -another significant~~

1 difference is that CF decreases (CTP increases) for low AOD condition but CF increases (CTP decreases)
2 for high AOD condition over ocean after the timestep, whereas CF increases (CTP decreases) for both low
3 and high AOD conditions over land after the timestep. We can conclude that the variation of cloud
4 properties after 3 hours depends little on the initial AOD over land, even though differences exist among the
5 urban clusters. The increase in afternoon cloud fraction over land is consistent with previous studies
6 concluding that continental warm clouds are likely to be well developed (Wang et al., 2014; Kourtidis et al.,
7 2015). The decrease in afternoon cloud cover over ocean confirms that the largest cover for marine clouds is
8 reached early in the morning (Meskhidze et al., 2009). Table 2 summaries the differences in cloud properties
9 between the Aqua and Terra overpasses for high and low AOD conditions over land and ocean during the
10 time period 2008-2011+2017, respectively.

CF	+	—+	—+	-	+	-
CTP	-	—	—	+	-	—

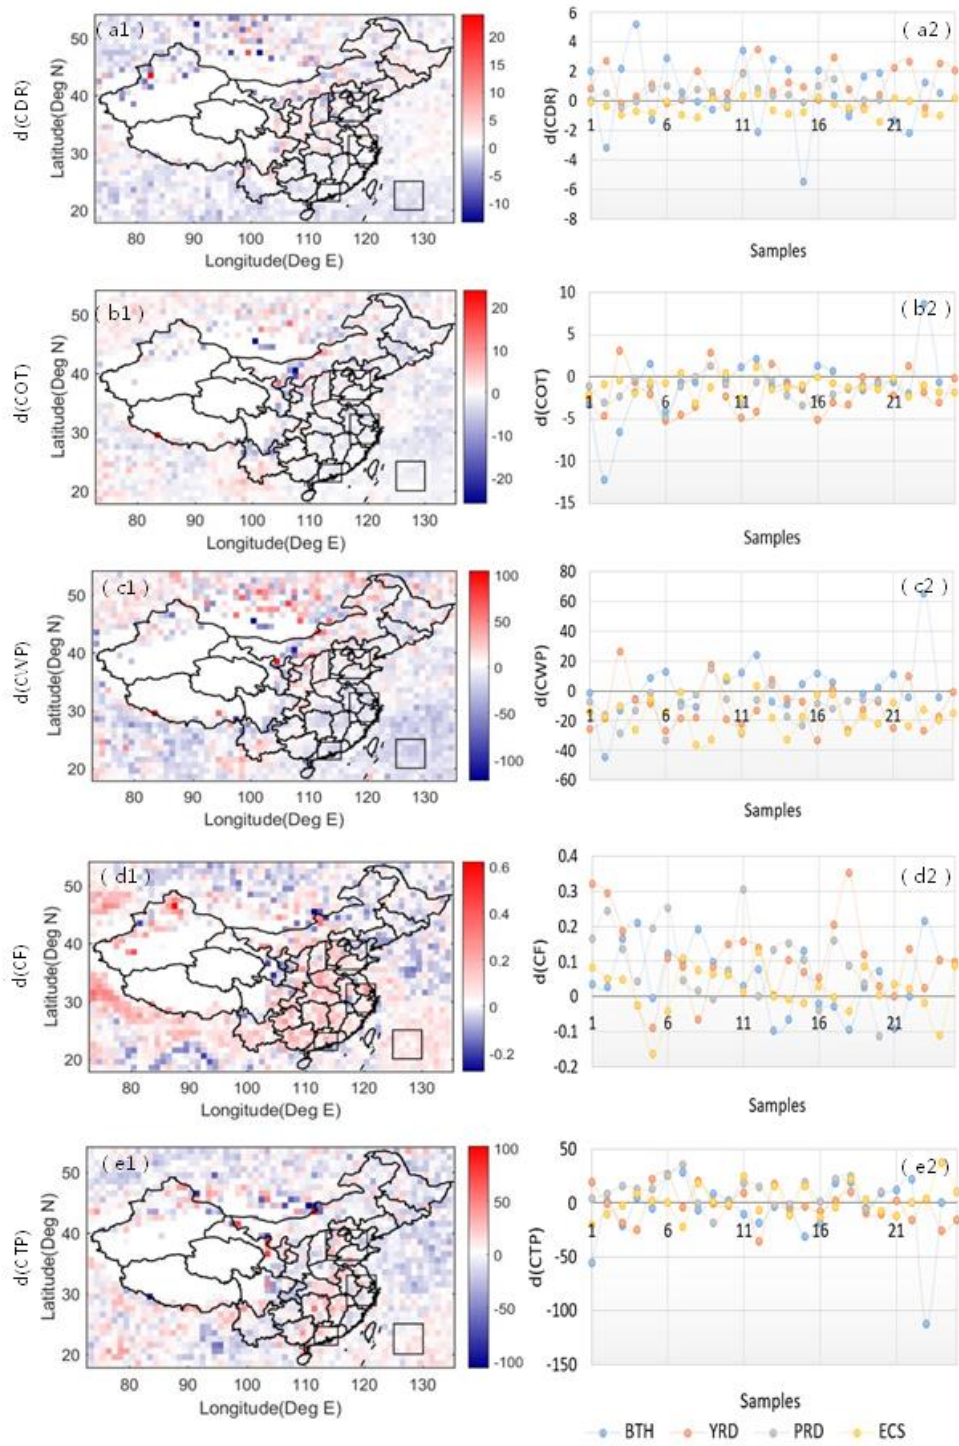

注: '+' indicates increasing, '-' indicates decreasing, '-' indicates the response of cloud properties to the increasing AOD is not significant or vague. '-' indicates the difference between the mean change in cloud properties (CF, COT, CWP, CDR and CTP) of the low and high AOD conditions over the timestep is small. L_AOD and H_AOD represent the low and high aerosol conditions, respectively.

4.3 The difference between the mean changes in cloud properties for low and high AOD over the timestep

The differences between the mean changes in cloud properties (CF, COT, CWP, CDR and CTP) between the Terra and Aqua overpasses in high and in low AOD conditions (d(Cloud_X) as defined in Section 3.2) are investigated to identify the effect of aerosol particles on the cloud properties. Figure 6-7 shows the differences between the mean change in cloud properties at low and high AOD conditions during the two observations at 10:30 and 13:30.

Figure 6-7 shows that the values of d(CDR) vary around zero over the three urban clusters are not mostly positive or negative, which indicates that during in high and low AOD conditions over land the change variation in CDR during the three hours between the MODIS/Terra and Aqua overpasses is similar. Over the ECS the values of d(CDR) also vary around zero are negative positive, which indicates that the CDR of in high AOD conditions decreases as much more than during low AOD conditions as that of low AOD over ocean. Wang et al. (2014) also reported that a negative correlation between CDR is negatively associated with AOD over the ECS, agreeing in accordance with the Twomey effect. Furthermore, CDR tends to be smallest in polluted and strong-inversion environments, an outcome in good agreement with the findings of Matsui et al. (2006). Most of the d(COT) values are negative over the four regions, especially for the YRD, PRD and ECS. This shows that the COT increases less in high AOD conditions than in low AOD conditions, over both land and ocean, which is contrast with the findings of Meskhidze et al. (2009). Likewise, the values of d(CWP) are almost all negative over the four regions although over the BTH urban cluster the values are less are not clear negative than over the other clusters and a number of positive values is observed. This indicates that in high AOD conditions the CWP increases less during the timestep than in at low AOD conditions, a result in accordance with the conclusion that higher LTS is linked with a slightly lower CWP (Matsui et al., 2006). We can conclude that the variation trend of COT and CWP after 3 hours depends little on the initial AOD, but the initial AOD conditions can affect the amplitude of

1 variation of COT and CWP. Meanwhile, the values of $d(CF)$ are larger-smaller than zero over the BTH
2 urban cluster and the ECS. This shows that the cloud fraction in high AOD conditions over the BTH
3 increases and ECS decreases much more-less than that in low AOD conditions. However, Meskhidze et al.
4 (2009) found that an increased of the- aerosol concentration may lead to enhanced reduction of
5 afternoon cloud coverage and optical thickness for marine stratocumulus regions off the coast of
6 California, Peru, and southern Africa. Therefore, the connection between AOD and variation of
7 cloud cover could be a response to regional-scale changes in aerosol covarying with
8 meteorological conditions. The value of $d(CF)$ is overall positive over landthe YRD and PRD, which
9 indicates that over the YRD and PRDland in high AOD conditions the cloud cover increases much more
10 than the cloud cover decreases in low AOD conditions. However, compared with the variation of $d(CF)$
11 over the BTH, the variations of $d(CF)$ over the YRD, PRD and ECS regions show a less clear pattern with
12 different behaviors. Mauger and Norris (2007) have shown that scenes with large AOD and large cloud
13 fraction experienced greater LTS. -As regards CTP, we find that the values of $d(CTP)$ are positive over the
14 BTH and PRD urban cluster, but the values of $d(CTP)$ over the other two regions do not show a clear
15 pattern-negative over the YRD and ECS regions. ItThis indicates that in high AOD conditions over the PRD
16 region the CTP increases much more than the CTP decreases in low AOD conditions. In addition, the behavior
17 $d(CTP)$ over the BTH urban cluster is variable with both negative and positive values. Overall, even though
18 there are large variations of $d(CTP)$ with increasing AOD over the three urban clusters, it seems that the
19 value of $d(CTP)$ is negative over land, indicating that in high AOD conditions over land the CTP decreases
20 less than in low AOD conditions. We can conclude that the variation in $d(Cloud_X)$ is different for
21 continental and oceanic clouds. This applies to CDR, cloud fraction (CF) and CTP, but not to COT and CWP.
22 Table 2 summarizes the differences between the mean changes in cloud properties for low and high AOD
23 over the timestep of 3 hours.
24 Based on the above findings, we conclude that over the ECS the values of CDR, CWP and CTP are smaller
25 but the values of COT and CF are larger in high AOD conditions. After the 3 hours timestep, CDR, CF
26 and CTP become smaller, irrespective of the AOD. Furthermore, CDR decreases much more in high AOD
27 conditions but CF and CTP decreases much more in high AOD conditions. In contrast, COT and CWP
28 become larger in both two-AOD conditions, more significantly in low AOD conditions. Over the urban
29 clusters, COT and CWP also increase over the timestep in both AOD conditions, especially for the low
30 AOD condition. For CF the values in low AOD conditions decrease in low AOD conditions over the
31 timestep. The CTP change behaves differently among the three urban clusters during the 3 hours.

1
 2 Figure 6-7 Spatial distributions (left, a1-e1) and sample time series (right, a2-e2) of $d(\text{Cloud}_X)$ (as defined in sect.
 3 3.2) for CDR, COT, CWP, CF and CTP over Eastern China during the time period 2008-~~2014~~2017.

1 4.4 Meteorological effects

2 In order to explore the initial meteorological effects on the correlations between AOD and the cloud
3 fraction, we determine the difference in mean cloud parameters between the high and low AOD
4 conditions at the end of the timestep ($d(\text{Cloud}_X)$) in meteorological variable space rather than in
5 longitude-latitude space. Therefore, we define high and low AOD as the highest and lowest quartile
6 for each bin of the meteorological parameters, respectively. Figure 7-8 shows the effect of meteorological
7 factors (PVV, RH, ~~LST-LTS~~ and initial cloud fraction) on the $d(\text{CF})$ when the cloud cover increases
8 ($\Delta\text{Cloud}_X > 0$) under both low and high AOD conditions over land after the 3 hours timestep. Figure 9
9 shows the effect of meteorological factors on the $d(\text{CF})$ when the cloud cover decreases ($\Delta\text{Cloud}_X < 0$)
10 under both low and high AOD conditions over land after the 3 hours timestep over land. From both
11 figures we find that almost all the values of $d(\text{CF})$ values are positive, indicating that the variations of CF
12 are larger in high AOD than that in low AOD after the 3 hours timestep over land.

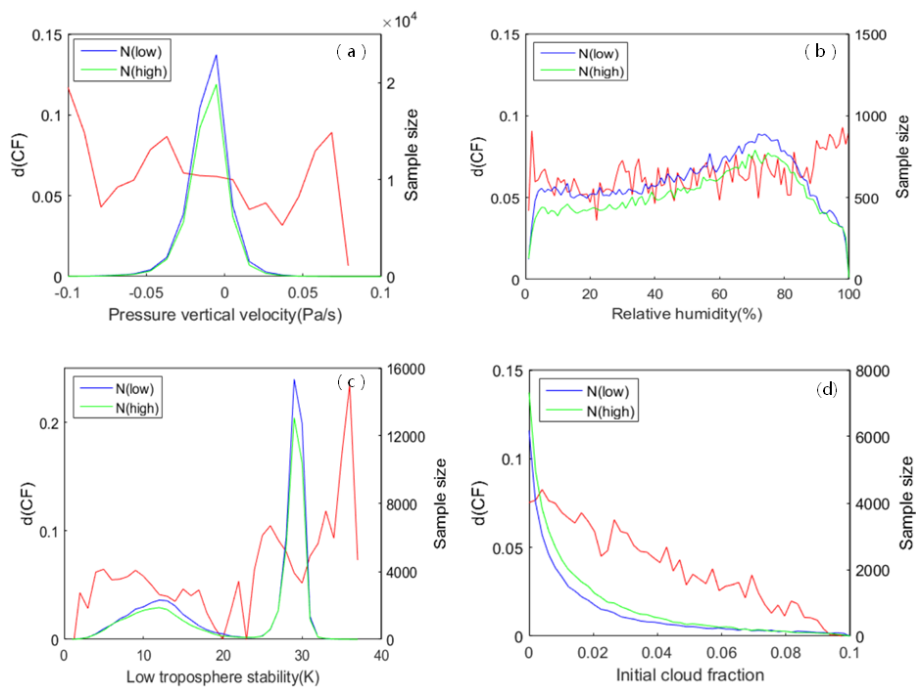

13 The PVV, a measure of dynamic convection strength, is very important for cloud formation. The
14 presence of upward motion, as indicated by negative PVV, can enhance the interaction between aerosol
15 particles and clouds as it promotes vertical mixing of the aerosol particles and thus reach the cloud
16 condensation level where they grow into cloud droplets, makes the ambient environment favorable for
17 cloud formation, and vice versa (Jones et al., 2009). Figure 78(a) shows that the $d(\text{CF})$ increases
18 decreases with the PVV over the range from -0.05 Pa s^{-1} to 0.05 Pa s^{-1} when the PVV is negative as
19 cloud cover increases in both two conditions over the 3 hours timestep. In contrast, the $d(\text{CF})$
20 decreases with the PVV when the PVV is larger than zero. This indicates that the weaker downward
21 motion and stronger upward motion of air parcels makes the difference between the increment of cloud
22 cover in high AOD conditions and in low AOD conditions larger. I, in other words, the increase rate of cloud
23 cover is larger for high AOD under stronger upward motion of air parcels. Jones et al. (2009)
24 revealed showed that stronger upward motion of air parcels can promote the cloud formation in both high
25 and low AOD conditions, but they did not report the increase rate of cloud formation in both two AOD
26 conditions. can enhance the cloud cover much more in conditions with high AOD than in conditions with
27 low AOD. While cloud cover decreases in both two conditions over the 3 hours timestep, Figure 9(a)
28 shows that the $d(\text{CF})$ increases with the PVV over the range from -0.05 Pa s^{-1} to 0 Pa s^{-1} and decreases

1 with the PVV over the range from 0 Pa s⁻¹ to 0.05 Pa s⁻¹. This indicates that the decrease rate of cloud
2 cover is smaller for high AOD both under stronger upward motion of air parcels and stronger downward
3 motion of air parcels. Outside of this range of PVV values the relationship becomes harder to determine
4 due to the reduction in data volumes in both cases. However, the relative increase in cloud cover is
5 smaller in the presence of downward motion of air parcels in high AOD environment than in low AOD
6 environment. Figure 78(b) shows that the d(CF) decreases with increasing RH when RH is lower than
7 92.20%. This implies that the increase rate of cloud cover is smaller for high AOD cloud cover increases
8 much more in low AOD environment than in high AOD environment with increasing RH. However,
9 when RH is larger than 20.92%, the increase rate of cloud cover is larger for high AOD with increasing
10 RH. A strong increase of d(CF) occurs due to activation of CCN and formation of clouds (Feingold et
11 al., 2003; Liu et al., 2017). It should be noted that the variation of d(CF) with increasing RH above
12 around 80% is uncertain as the sample sizes of high and low AOD conditions are small. On the
13 contrary In contrast, the values of d(CF) values becomes smaller with increasing RH over the whole RH
14 range (See Figure 9(b)), indicating that the decrease rate of cloud cover is smaller for high AOD than that
15 for low AOD with increasing RH.

16 The LTS is an indicator for the mixing state of the atmospheric layer adjacent to the surface. It describes
17 to some extent the atmosphere's tendency to promote or suppress vertical motion (Medeiros and Stevens,
18 2011), which in turn affects cloud properties (Klein and Hartmann, 1993). A positive LTS is associated
19 with a stable atmosphere in which vertical mixing is prohibited; negative PVV indicates local upward
20 motion of air parcels. Low LTS represents an unstable atmosphere and high LTS represents a stable
21 atmosphere. Both Figure 78(c) and Figure 9(c) shows that the d(CF) increases and then decreases with
22 increasing LTS when LTS is lower than 20.27, but increases decreases with increasing LTS for higher
23 values (LTS >20). High LTS indicates a strong inversion, which prevents vertical mixing and cloud
24 vertical extent, maintaining a well mixed and moist boundary layer and providing an environment which
25 favors the development of a low cloud cover, especially in an environment with high AOD
26 concentrations. However, the sample sizes of high and low AOD conditions are small extremely
27 disproportionate when LTS is higher larger than 27 20. Therefore, it is difficult to reach a conclusion
28 from the relationship between d(CF) and LTS is uncertain hard to make a conclusive determination when
29 LTS is larger than 20. Figure 78(d) shows that there is weak a strong negative relationship between d(CF)
30 and initial cloud fraction. The effect of initial cloud fraction on d(CF) is not clear. The d(CF) increases

1 with increasing initial cloud cover, even though the data volume becomes smaller over the range from 0
 2 to 1.0. It infers This implies that the increase rate of cloud cover becomes smaller for high AOD with an
 3 increase of the initial cloud cover in conditions. Likewise, Figure 9(d) also shows that d(CF) decreases
 4 with increasing initial cloud cover, indicating that the decrease rate of cloud cover becomes larger for
 5 high AOD with increasing initial cloud cover. This phenomenon is different from the observation of ed
 6 weak relationship between d(CF) and initial cloud fraction in the oceanic shallow cumulus regime
 7 (Gryspeerdt et al., 2014). It may be result from the combination of above two cases.

8

9

10 Figure 7-8. Variation of d(CF) (red) as function of initial meteorological parameters and cloud fraction for warm
 11 clouds when the cloud cover increases under both low and high AOD conditions over land after the 3 hours timestep
 12 over land. The distribution of points for low (blue) and high (green) AOD as a function of meteorological parameters
 13 is shown by the solid lines. This plot is composed from MODIS data (including Terra and Aqua) for all warm cloud
 14 points over the years 2008-~~2011~~2017. Meteorological parameters are plotted along the horizontal axis, the left
 15 vertical axis denotes d(CF) and the right vertical axis denotes the number of high and low AOD samples.

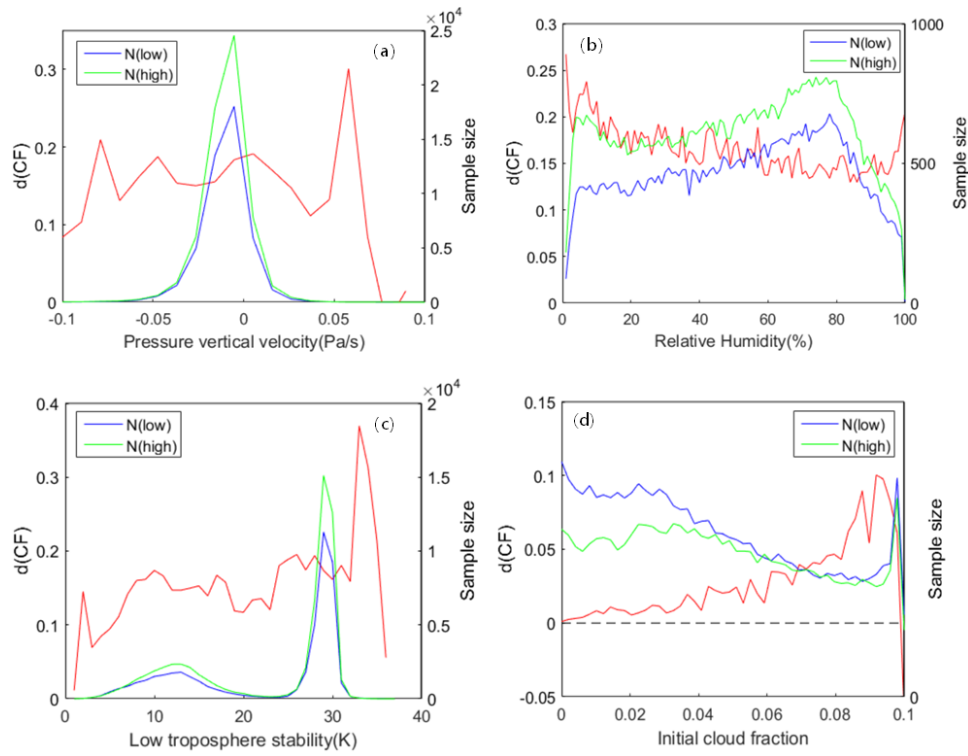

Figure 9 The same as Fig. 8 but for warm clouds when the cloud cover decreases under both low and high AOD conditions over land after the 3 hours timestep over land.

5 Conclusions

The large anthropogenic emissions in eastern China render this area an important hotspot for studying how cloud microphysical properties are affected by anthropogenic aerosols (Ding et al., 2013). In this work, based on the near-simultaneous aerosol and cloud retrievals provided by MODIS, together with the ERA Interim Reanalysis data, we investigated the effect of aerosol loading, using as indicated by AOD as a proxy, on aerosol-cloud interactions. Aerosol-cloud interaction was studied over three major urban clusters in eastern China and over one area over the Eastern China Sea. These four areas are representative of different climatic regions and pollution levels. Data over these four study areas were collected for the years 2008 to 2017, and analyzed in a statistical sense using statistical methods. Both MODIS/Terra and MODIS/Aqua data were used to study the difference of in cloud properties between the morning and the early afternoon, i.e. with a time difference of 3 hours.

In order to reduce the differences of in the initial conditions-distributions of cloud and meteorological parameters between high and low AOD conditions at the start of the timestep, normalized histograms of these cloud properties and meteorological parameters were made for high and low AOD conditions

1 following the method described by Gryspeerd et al., (2014). After that, the difference between cloud
2 properties (CDR, COT, CWP, CF and CTP) in high and low AOD conditions during the Terra overpass
3 at 10:30 LT for each $1^\circ \times 1^\circ$ grid was investigated. We looked at statistics for the 104-years dataset and
4 found that different regions with various aerosol emission levels, aerosol types and different climate
5 characteristics show different patterns of ACI. The ACI is more complex over land (BTH, YRD and PRD)
6 than over ocean (ECS). Next, the mean change in cloud properties during the 3 hours between the
7 observations in low and high AOD conditions, as provided by the differences in the observations by
8 MODIS/Terra (morning) and MODIS/Aqua (afternoon) overpasses, were examined and differences
9 were analyzed. The results show that the COT and CWP over land and ocean were increased after the 3
10 hours timestep over land and ocean, irrespective of the initial AOD conditions. in low and high AOD
11 conditions the variation of cloud properties between the two observations behave similarly (increase or
12 decrease). In general, the variation of cloud properties over the urban clusters is similar to that over ocean.
13 Two significant differences are found between land and ocean areas. One is that CDR increases over land
14 but decrease over ocean after the 3 hour period, another significant difference is that CF decreases (CTP
15 increases) for low AOD condition but CF increases (CTP decreases) for high AOD condition over ocean
16 during the timestep, whereas CF increases (CTP decreases) during that period for both low and high
17 AOD conditions over land. Furthermore, we investigated the difference between the mean change in
18 cloud properties (CDR, COT, CWP, CF and CTP) in low and high AOD conditions between the two
19 observations. We found that the variation in $d(\text{Cloud}_X)$ is different for continental and oceanic clouds.
20 This applies to CDR, cloud fraction and CTP, but not to COT and CWP. Both COT and CWP increase
21 over land and ocean after the timestep, irrespective of the AOD. The variation trend of COT and CWP
22 after 3 hours depends little on the initial AOD, but the initial AOD conditions can affect the amplitude
23 of variation of COT and CWP.
24 Constrained by relative humidity and boundary thermodynamic and dynamic conditions, the variation of
25 $d(\text{CF})$ in response to aerosol abundance over land was also analyzed. There are two cases were
26 considered: (1) when the cloud cover increases under both low and high AOD conditions after the 3 hours
27 timestep; (2) when the cloud cover decreases under both low and high AOD conditions after the 3 hours
28 timestep. From both two cases, we find that almost all the values of $d(\text{CF})$ values are positive, indicating
29 that the variations of CF are larger in high AOD than that in low AOD after the 3 hours timestep. The
30 results show that cloud cover increases much for high AOD under stronger upward motion of air parcels;

1 ~~Meanwhile, the increase rate of cloud cover is larger for high AOD with increasing RH when RH greater~~
2 ~~than 20%. scenes with large cloud fraction experience large AOD and stronger upward motion of air~~
3 ~~parcels and large RH. of~~ With regarded to the effect of LTS on the change of cloud cover, scenes with
4 ~~large cloud fraction changevariation experience large AOD and large LTS when LTS smaller than 10.~~
5 ~~Conversely, scenes with smaller cloud fraction changevariation experience large AOD and large LTS~~
6 ~~when LTS larger than 10 and smaller than 20. We also find that smaller increase rate of cloud fraction~~
7 ~~occurs when scenes experience larger AOD and larger initial cloud coverins,the presence of upward~~
8 ~~motion of air parcels can enhance the cloud cover much more in high than in low AOD conditions. In~~
9 ~~contrast, the cloud cover increases much more with increasing RH in clean atmospheric conditions than~~
10 ~~in polluted atmospheric conditions. Meanwhile, stable atmospheric conditions favor the development of~~
11 ~~a low cloud cover, especially in high AOD conditions. A statistical analysis of the relation between $d(CF)$~~
12 ~~and initial cloud fraction shows a weak negative relationship between $d(CF)$ and initial cloud fraction.~~

13 In summary, whilst we have reduced the error due to meteorological effects on aerosol retrieval,
14 meteorological covariation with the cloud and aerosol properties is harder to remove. As aerosol-cloud
15 interaction is a complex problem, it is important to synergistically use multiple observation products and
16 atmospheric models to explore the mechanisms of aerosol-cloud interaction. Therefore, further analysis
17 can be carried out in future work.

1 Reply to comments on “Satellite-based estimate of the
2 variability of warm cloud properties associated with aerosol and
3 meteorological conditions”

4
5 October 30, 2018

6
7 We thank the reviewer's thoughtful comments which are helpful not only for this
8 manuscript but also for our future research. Our replies for all the comments are
9 shown below.

10
11 **Major points**

12 **1. Comments: (1) The authors make use of a technique previously used to**
13 **investigate possible links between aerosol and cloud fraction, extending it to look**
14 **at the development of other cloud properties. A key part of this method involves**
15 **making sure that the starting state similar as possible for high and low aerosol**
16 **environments and then investigating the difference between them. If this method**
17 **works as intended, the mean change in cloud properties over the timestep should**
18 **be a function only of local meteorology and there should be no difference in the**
19 **cloud properties between the high and low aerosol populations at the start time. I**
20 **am therefore unclear what is being shown in section 4.1, where a difference**
21 **apparently exists. Are the authors following the method of Gryspeerdt et al**
22 **(2014), or have they created a new method? If the authors are just looking at the**
23 **relationship between AOD and cloud properties, how have they accounted for**
24 **the impact of local meteorology (e.g. Quaas et al, ACP, 2010)?**

25 **Answer:** Normalised histograms of cloud properties for the high and low AOD
26 populations are made for the whole region (Section 3.1), because the data volume
27 based on each $1^\circ \times 1^\circ$ location is relatively small. However, the difference between
28 the cloud properties for low and high AOD at the start time is based on each $1^\circ \times 1^\circ$
29 location (Section 4.1). So the difference of the cloud properties between the low and
30 high AOD at the start time still exist and is not zero. In order to make the reader
31 understand, text was added as follows.

32 Page 5 lines 37-39 and page 6 lines 1-2, : Text was added as: ' Note that here and in
33 the following sections, normalised histograms of cloud properties for the high and low
34 AOD populations are made for the whole region (Section 3.1), because the data
35 volume based on each $1^\circ \times 1^\circ$ location is relatively small. However, the difference
36 between the cloud properties for low and high AOD at the start time is based on each
37 $1^\circ \times 1^\circ$ location (Section 4.1). So the difference of the cloud properties between the
38 low and high AOD at the start time is not zero.'

39 Page 9, line 15-17: Text was added as: ' Although normalized histograms of

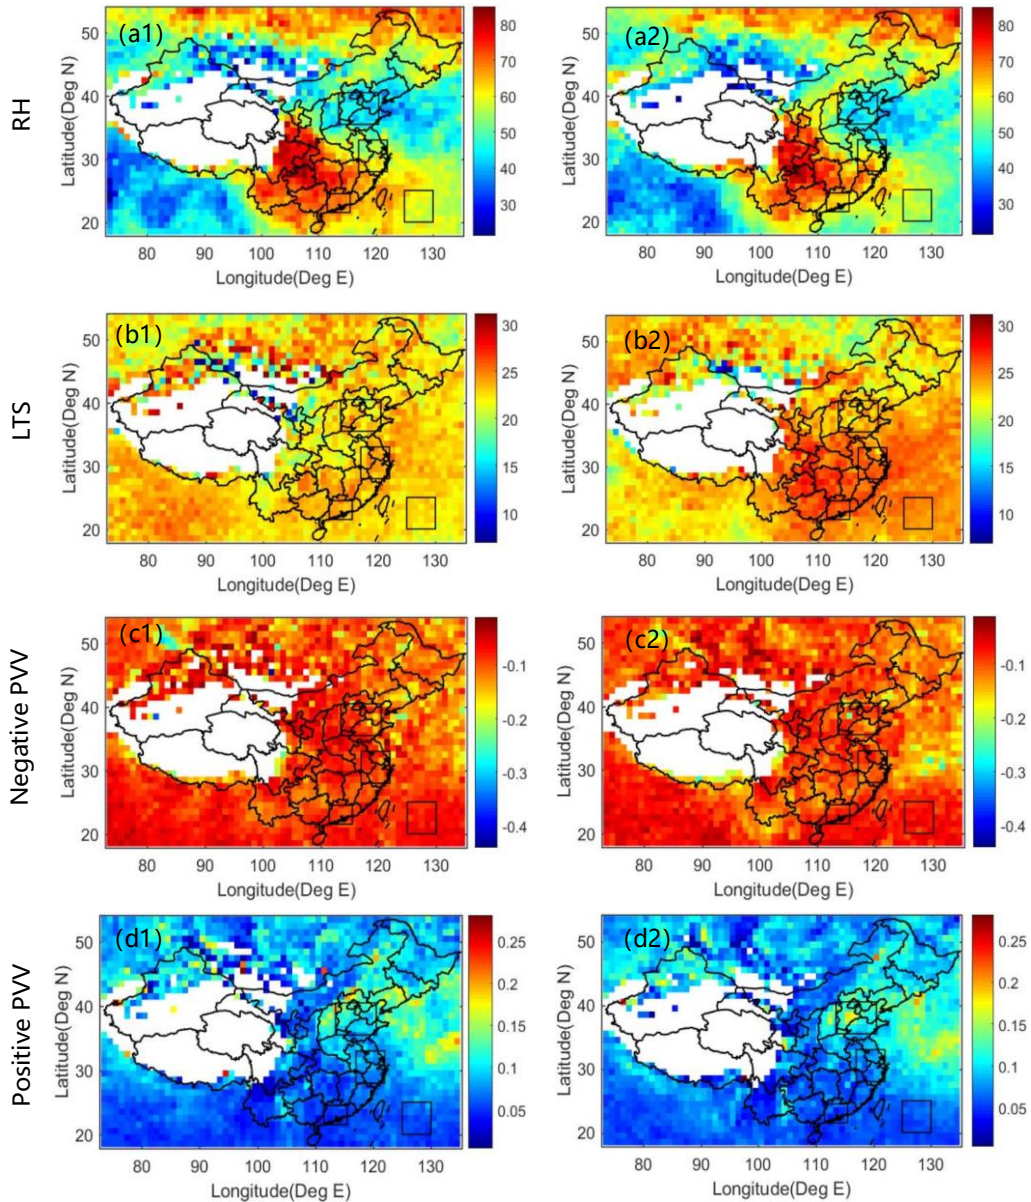

1 meteorological parameters are made for high and low AOD conditions at the start
2 time, the normalization described in Sect. 3.1 is based on the whole region.
3 Differences in meteorological conditions may still occur between each $1^\circ \times 1^\circ$ grid
4 cell.’

5 Meanwhile, in order to consider the effect of meteorological conditions on the
6 relationship between aerosol and cloud further, we analyze the meteorology of the
7 different regions in Section 4.2 (see page 9-10). This new Section 4.2 “The
8 meteorology of the four target regions” reads:

9 **4.2 The meteorology of the four target regions**

10 The meteorological and aerosol effects on clouds are reported to be tightly connected,
11 and this connection must be accounted for in any study of aerosol-cloud interactions
12 (Stevens and Feingold, 2009; Koren et al., 2010). Although normalized histograms of
13 meteorological parameters are made for high and low AOD conditions at the start
14 time, the normalization described in Sect. 3.1 is based on the whole region.
15 Differences in meteorological conditions may still occur between each $1^\circ \times 1^\circ$ grid
16 cell. In this study, we analyze the meteorology of the different regions, in support of
17 the interpretation of the regional variation of the relationships between aerosols and
18 clouds.

19

1

2 Figure 4 Spatial distributions of meteorological parameters (top to bottom: RH, LTS, positive PVV
 3 and negative PVV) at the start time of the timestep (MODIS/Terra) for low AOD conditions (left,
 4 a1-d1) and for high AOD conditions (right, a2-d2). All the data are averaged over all years between
 5 2008 and 2017.

6 The spatial variations of the aerosol and cloud properties over the four regions,
 7 averaged over the years 2008-2017, are shown in Fig. 4. Over the urban clusters, we
 8 can see an increasing north-south pattern in RH and LTS, with the lowest values
 9 found in the PRD. For the negative PVV, the spatial distributions for the low and high
 10 AOD situations are remarkably similar, with the highest values over the BTH and
 11 decreasing toward the south to near zero over the PRD. In contrast, the positive PVV
 12 is smallest over the BTH, with little variation over the study area. Overall, the
 13 meteorological parameters over the YRD and PRD are similar to those over the ECS,
 14 irrespective of the AOD. Furthermore, the LTS is significant larger in the high AOD
 15 conditions for all the four regions. Zhao et al. (2006) proposed that the enhancement

1 in the atmospheric stability tends to depress upward motion and precipitation, leading
2 to an increase in aerosol particles. The spatial distributions of both positive and
3 negative PVV in the low AOD conditions are similar to those in the high AOD
4 conditions.

5
6 **2. Comments: (2)** Similarly, it is not clear what section 4.2 is showing. While the
7 title states that it is discussing the 'mean change', it is apparently also
8 investigating the difference between high and low AOD. If this is the case, could
9 it not be merged with section 4.3, which is explicitly about the difference in
10 relation to the aerosol environment? I would expect that the difference in the
11 development between the regions would be a function of local meteorology. If 4.2
12 is intended to be about the mean cloud development, perhaps it could be used to
13 better describe the meteorology of the different regions, helping the
14 interpretation of the regional variation of the results in section 4.3.

15 **Answer:** Yes, we agree with your suggestions. Section 4.2 was merged with Section
16 4.3 (as new Section 4.3, see pages 10-15), explicitly examining the difference of
17 cloud properties in relation to aerosol environment. Furthermore, new Section 4.2 was
18 added (see response to question 1) to describe the meteorology of the four target
19 regions, in support of the interpretation of the regional variation of relationship
20 between aerosol and cloud (see page 9-10 in the revised manuscript).

21
22 **3. Comments: (3)** While this work has the potential for producing interesting
23 results if the method is properly clarified, the results that are currently within
24 the paper are not set in the context of existing work, which makes them difficult
25 to interpret. The results in section 4.3 and not compared to section 4.1 or
26 previous work, meaning that potentially interesting results are missed. As some
27 examples, P13L14 suggests that there is little change in the CDR development as
28 a function of aerosol - this inability to detect the Twomey effect might mean that
29 this method is not suitable for investigating aerosol cloud interactions, or it could
30 mean that changes in CDR proceed via different pathways and timescales than
31 the CF changes observed in Gryspeerdt et al. (2014). Although the difference in
32 results over land and ocean was one of the key results of Gryspeerdt et al (2014),
33 other result are different - this work finds exactly the opposite dCF response to
34 relative humidity (section 4.4). This would again be an interesting result for
35 discussion that is missed as it is not set in context.

36 **Answer:** The variation of cloud properties to the aerosol environment has become
37 more clear by reanalyzing all the MODIS C6.1 data for the whole acquisition period
38 between 2008 and 2017, rather than MODIS C5.1 data from 2008 to 2011. This
39 change is shown throughout the revised manuscript (all the figures were
40 changed/modified in this respect). Following the reviewer's comments, the results in
41 Section 4.3 have been linked to Section 4.1 and compared to previous work.

42 Part of text in Section 4.3 was shown in follows (see page 14-15 in the revised
43 manuscript):

44 "Figure 7 shows that the values of d(CDR) over the three urban clusters are not

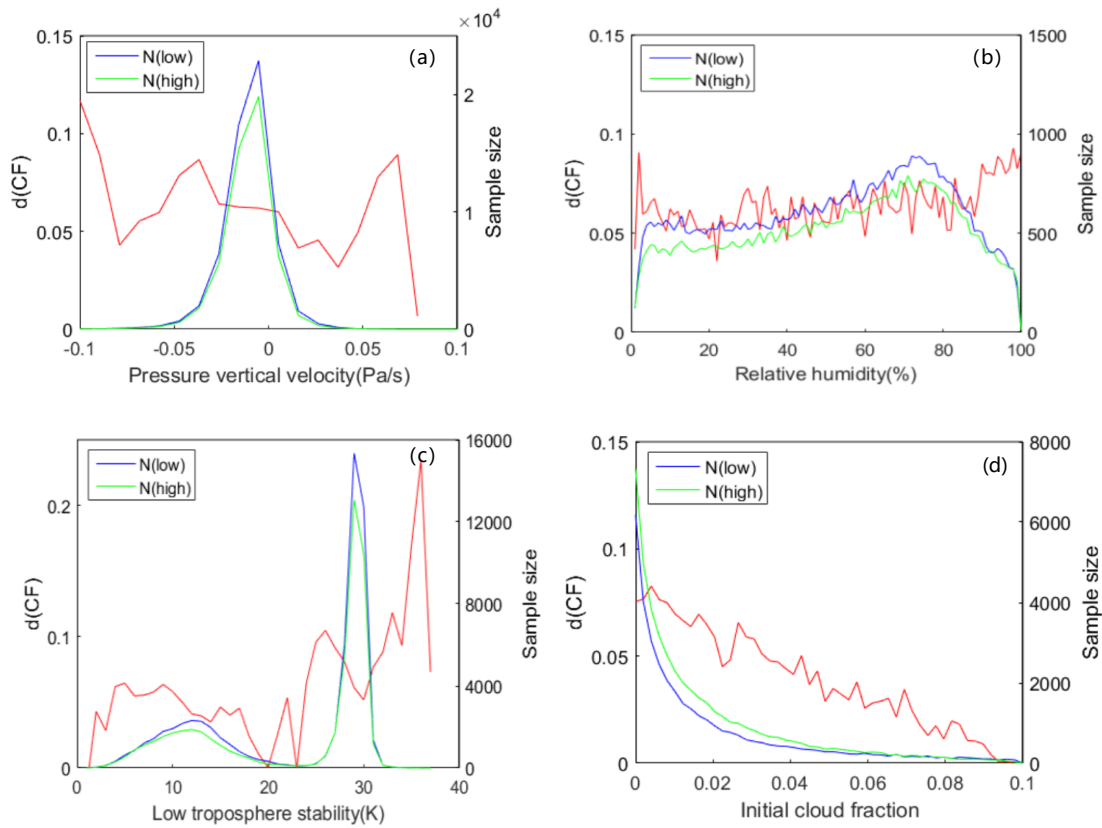

1 mostly positive or negative, which indicates that in high AOD conditions over land
2 the variation in CDR during the three hours between the MODIS/Terra and Aqua
3 overpasses is similar. Over the ECS the values of $d(\text{CDR})$ is positive, which indicates
4 that the CDR in high AOD conditions decreases much more than during low AOD
5 conditions over ocean. Wang et al. (2014) also reported a negative correlation
6 between CDR and AOD over the ECS, in accordance with the Twomey effect.
7 Furthermore, CDR tends to be smallest in polluted and strong-inversion environments,
8 an outcome in good agreement with the findings of Matsui et al. (2006). Most of the
9 $d(\text{COT})$ values are negative over the four regions, especially for the YRD, PRD and
10 ECS. This shows that the COT increases less in high AOD conditions than in low
11 AOD conditions, over both land and ocean, which is contrast with the findings of
12 Meskhidze et al. (2009). Likewise, the values of $d(\text{CWP})$ are almost all negative over
13 the four regions although over the BTH urban cluster the values are not clear. This
14 indicates that in high AOD conditions the CWP increases less during the timestep
15 than in low AOD conditions, a result in accordance with the conclusion that higher
16 LTS is linked with a slightly lower CWP (Matsui et al., 2006). We can conclude that
17 the variation trend of COT and CWP after 3 hours depends little on the initial AOD,
18 but the initial AOD conditions can affect the amplitude of variation of COT and CWP.
19 Meanwhile, the values of $d(\text{CF})$ are smaller than zero over the ECS. This shows that
20 the cloud fraction in high AOD conditions over ECS decreases less than that in low
21 AOD conditions. However, Meskhidze et al. (2009) found that an increase of the
22 aerosol concentration may lead to enhanced reduction of afternoon cloud coverage
23 and optical thickness for marine stratocumulus regions off the coast of California,
24 Peru, and southern Africa. Therefore, the connection between AOD and variation of
25 cloud cover could be a response to regional-scale changes in aerosol covarying with
26 meteorological conditions. The value of $d(\text{CF})$ is overall positive over the PRD, which
27 indicates that over the PRD in high AOD conditions the cloud cover increases much
28 more than the cloud cover decreases in low AOD conditions. Mauger and Norris
29 (2007) have shown that scenes with large AOD and large cloud fraction experienced
30 greater LTS. As regards CTP, we find that the values of $d(\text{CTP})$ are positive over the
31 BTH and PRD urban cluster, but the values of $d(\text{CTP})$ over the other two regions are
32 not significant. It indicates that in high AOD conditions over the PRD region the CTP
33 increases much more than the CTP decreases in low AOD conditions. We can
34 conclude that the variation in $d(\text{Cloud}_X)$ is different for continental and oceanic
35 clouds. This applies to CDR, cloud fraction (CF) and CTP, but not to COT and CWP.
36 Table 2 summarizes the differences between the mean changes in cloud properties for
37 low and high AOD over the timestep of 3 hours.

38 Based on the above findings, we conclude that over the ECS the values of CDR, CWP
39 and CTP are smaller but the values of COT and CF are larger in high AOD conditions.
40 After the 3 hours timestep, CDR, CF and CTP become smaller, irrespective of the
41 AOD. Furthermore, CDR decreases much more in high AOD conditions but CF and
42 CTP decreases much more in low AOD conditions. In contrast, COT and CWP
43 become larger in both AOD conditions, more significantly in low AOD conditions.
44 Over the urban clusters, COT and CWP also increase over the timestep in both AOD

1 conditions, especially for the low AOD condition. For CF the values in low AOD
 2 conditions decrease over the timestep. The CTP change behaves differently among the
 3 three urban clusters during the 3 hours.”

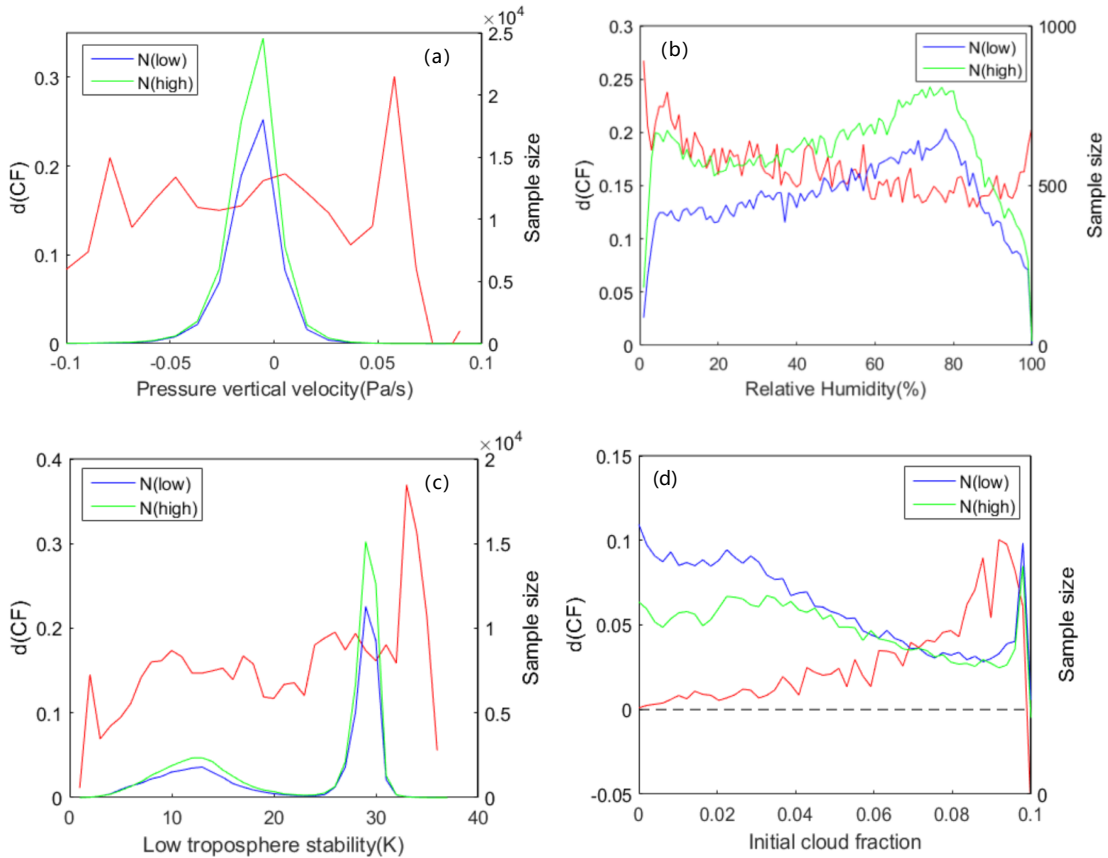

4 The sentence in P13L14 in old version manuscript is “Figure 6 shows that the values
 5 of $d(\text{CDR})$ vary around zero over the three urban clusters, which indicates that during
 6 high and low AOD over land the change in CDR during the three hours between the
 7 MODIS/Terra and Aqua overpasses is similar.” The sentence means that there are
 8 changes (increase or decrease) of CDR in both AOD conditions after 3 hours timestep,
 9 but the variation quantity is similar. So, it doesn’t indicate that this inability to detect
 10 the Twomey effect. As Figures 3(a1-a2) show, over the ECS, CDR is smaller at high
 11 AOD than at low AOD, which is consistent with Twomey’s effect. In contrast, over
 12 the three urban clusters, CDR is larger at high AOD. This behavior has been observed
 13 before for warm clouds in conditions with high AOD (Liu et al., 2017) and may result
 14 from the intense competition for the available water vapour and the evaporation of
 15 smaller droplets as a consequence of the high aerosol abundance over these regions
 16 (Yuan et al., 2008; Wang et al., 2014; Tang et al., 2014; Liu et al., 2017).

17 The effects of initial cloud fraction and meteorological conditions on the change in
 18 CF under low and high AOD conditions after the 3 hours timestep over land are also
 19 explored. In our new version manuscript, there are two cases are considered: (1) when
 20 the cloud cover increases ($\Delta\text{Cloud}_X > 0$); (2) when the cloud cover decreases
 21 ($\Delta\text{Cloud}_X < 0$). The $d(\text{CF})$ (see Section 3.2) response to relative humidity is different
 22 for both cases (see Section 4.4 in the revised manuscript). However, the results of
 23 Gryspeerd et al. (2014) are based on the combination of the two cases.

24

1 Figure 8. Variation of $d(\text{CF})$ (red) as function of initial meteorological parameters and cloud
 2 fraction for warm clouds when the cloud cover increases under both low and high AOD conditions
 3 after the 3 hours timestep over land. The distribution of points for low (blue) and high (green) AOD
 4 as a function of meteorological parameters is shown by the solid lines. This plot is composed from
 5 MODIS data (including Terra and Aqua) for all warm cloud points over the years 2008-2017.
 6 Meteorological parameters are plotted along the horizontal axis, the left vertical axis denotes $d(\text{CF})$
 7 and the right vertical axis denotes the number of high and low AOD samples.

8
 9 Figure 9 The same as Fig. 8 but for warm clouds when the cloud cover decreases under both low and
 10 high AOD conditions after the 3 hours timestep over land.

11
 12 **4. Comments: (4) I am not clear of the purpose of choosing the different regions**
 13 **in this work. They are explained in section 2, but very little reference is made to**
 14 **these meteorological differences later in the paper. Other than noting that the**
 15 **aerosol-cloud relationships are different in these regions, there is little discussion**
 16 **of why there is a difference. As variations have previously been noted in the**
 17 **strength of aerosol-cloud relationships, it would be good to include some**
 18 **discussion as to why they are different. This would help this paper build on the**
 19 **previous literature in this area.**

20 **Answer:** Yes, following the reviewer's comments, we add the meteorology of the
 21 four target regions in new Section 4.2, in support of the interpretation of the regional
 22 variation of relationship between aerosol and cloud. Furthermore, we have discussions
 23 of those different aerosol-cloud relationships in different regions and gave possible

1 reasons (see pg.11 lines 12-17 in the revised manuscript).

2 In order to include some discussion as to why they are different, text was added
3 as: 'From the perspective of considering all urban clusters (BTH, YRD and PRD),
4 both COT and CWP increase over land during the 3 hours timestep for both low and
5 high AOD. Overall, the variation in cloud properties after the timestep over BTH is
6 less significant than over the YRD and PRD for both low and high AOD conditions.
7 This may result from less humid and more unstable atmospheric environments over
8 the BTH than over the other two urban clusters (as shown in Section 4.2).' in the Page
9 11, line 12-17.

10 11 **Specific comments**

12 **1. Comments: (1) Page 1, Line 39: Twomey 1974/77?**

13 **Answer:** We made this change (see page 2, lines 3-4). "Due to interactions with
14 aerosols, the climatic effects of clouds are further complicated (Rosenfeld, 2000;
15 Twomey, 2007)" has been changed to "Due to interactions with aerosols, the climatic
16 effects of clouds are further complicated (Rosenfeld, 2000; Twomey, 1974; Twomey,
17 1977)."

18 19 **2. Comments: (2) Page 2, Line 3: a smaller droplet radius does not always result** 20 **in precipitation suppression, especially if the warm rain frequency is already low** 21 **(e.g. Muelmenstaedt et al., GRL, 2015)**

22 **Answer:** "Thus, cloud albedo increases and the smaller cloud droplet effective radius
23 results in the suppression of precipitation, which in turn results in a longer cloud
24 lifetime, and maintaining a larger liquid water path (Albrecht, 1989; Feingold et al.,
25 2001)" has been changed to "Thus, cloud albedo increases and the smaller cloud
26 droplet effective radius in most cases results in the suppression of precipitation, which
27 in turn results in a longer cloud lifetime, and maintaining a larger liquid water path
28 (Albrecht, 1989; Feingold et al., 2001)" in the revised manuscript (see page2, line
29 8-10).

30 31 **3. Comments: (3) Page 4, Line 1: Why not use collection 6 data? There is also** 32 **almost four times as much MODIS daily data available as it being used here.** 33 **Why has this specific time period been chosen? A larger data record would** 34 **improve the statistical significance of this work.**

35 **Answer:** Following the reviewer's comments, we use collection 6.1 data and
36 reanalyze all the data for the whole acquisition period between 2008 and 2017, rather
37 than C5.1 data from 2008 to 2011. Therefore, the variation of cloud properties to the
38 aerosol environment has been changed and more clear. This issue is shown
39 throughout the revised manuscript (all the figures were changed/modified in this
40 respect).

41 42 **4. Comments: (4) Page 4, Line 24: Why is aerosol optical depth used? Many** 43 **previous studies have that it had severe limitations proxy for CCN (e.g. Penner et** 44 **al, PNAS, 2011)**

1 **Answer:** The average CCN concentrations show a remarkable correlation to the
2 corresponding AOT values, it provides an easily measured proxy for CCN
3 concentration (Andreae, 2009). Meanwhile, in the present study the use of AI would
4 not be appropriate, because our study is conducted mostly over land areas. This has to
5 do with the use of the Ångström exponent in the derivation of AI, namely, the
6 Ångström exponent is not reliable over land areas. We quote a personal
7 communication with L. Remer (20 June 2010), NASA GSFC: “Ångström over land is
8 not reliable and we recommend strongly not to use it”; hence, AOD is used in our
9 study (Kourtidis et al., 2015).

10
11 **5. Comments: (5) Page 5, Line 2: ‘representative of typical thermodynamic**
12 **conditions’ it is not clear what this means.**

13 **Answer:** “...which is representative of typical thermodynamic conditions (Klein and
14 Hartmann, 1993).” has been changed to “...which can be regarded as a measure of the
15 strength of the inversion that caps the planetary boundary layer (Klein and Hartmann,
16 1993; Wood and Bretherton, 2006)” in the revised manuscript (see page 4, line
17 30-31).

18
19 **6. Comments: (6) Page 6, Lines 1: Are all parameters considered at the same**
20 **time? Gryspeerdt et al, also used meteorological parameters normalization.**

21 **Answer:** Yes, normalized histograms of cloud properties and meteorological
22 parameters are made for high and low AOD conditions following the method
23 described by Gryspeerdt et al. (2014).

24
25 **7. Comments: (7) Page 6, Line 2: Normalisation by cloud fraction makes the**
26 **biggest difference in what?**

27 **Answer:** We made this change (see page 5 lines 34-35). “...even though we find that
28 the normalization for the cloud fraction made the biggest difference by far.” has been
29 changed to “Among those cloud properties, this process of normalization has the
30 greatest effect on the cloud fraction and its dependence on aerosol-cloud interaction.”

31
32 **8. Comments: (8) Page 6, Line 2: Does this mean this normalization method is**
33 **applied throughout this work?**

34 **Answer:** Yes, the sentence means the normalization method is applied throughout the
35 work. And “In the further analysis, we only take a subset of original data by removing
36 random samples until the histograms are similar.” has been changed to “Throughout
37 the work, we only take a subset of original data by removing random samples until the
38 histograms are similar.” (see page 5, line 35-36 in the revised manuscript)

39
40 **9. Comments: (9) Page 6, Line 24: As mentioned earlier should the difference**
41 **between the cloud properties at the start time not be zero?**

42 **Answer:** Normalised histograms of cloud properties for the high and low AOD
43 populations are made for the whole region (Section 3.1), because the data volume
44 based on each $1^\circ \times 1^\circ$ location is relatively small. However, the difference between

1 the cloud properties for low and high AOD at the start time is based on each $1^{\circ} \times 1^{\circ}$
2 location (Section 4.1). So the difference of the cloud properties between the low and
3 high AOD at the start time is not zero (see response to question 1 in major points
4 section).

5
6 **10. Comments: (10) Page 7, Line 7, Perhaps also Yuan et al, ACP, 2008 (Increase**
7 **of cloud droplet size with aerosol optical depth: An observation and modeling**
8 **study, 10.1029/2007JD008632)**

9 **Answer:** We made this change (see page 7, line 6-8). "...may result from the intense
10 competition for the available water vapour and the evaporation of smaller droplets as
11 a consequence of the high aerosol abundance over these regions (Wang et al., 2014;
12 Liu et al., 2017)." has been changed to "...may result from the intense competition for
13 the available water vapour and the evaporation of smaller droplets as a consequence
14 of the high aerosol abundance over these regions (Yuan et al., 2008; Tang et al., 2014;
15 Wang et al., 2014; Liu et al., 2017)."

16
17 **11. Comments: (11) Page 7, Line 22: Many previous studies have shown links**
18 **between aerosol and cloud properties over China but it might be good to know**
19 **why these relationships are different.**

20 **Answer:** We made this change (see page 9 lines 1-8). Text are added as: "Some links
21 between aerosol and cloud in the four regions are different from those of previous
22 studies over China (Wang et al., 2014; Tang et al., 2014; Kourtidis et al., 2015; Liu et
23 al., 2017), which might be due to the use of different data sets (MODIS C6.1 versus
24 older versions), hypothesis and target areas characterized by complex aerosol
25 compositions and varying meteorological conditions. Overall, the result implies that
26 the interaction between aerosol particles and clouds is more complex and of greater
27 uncertainty over land (BTH, YRD and PRD) than over ocean (ECS). Jin and
28 Shepherd (2008) also noted that aerosol affect clouds more significantly over ocean
29 than over land. They suggested that dynamic processes related to factors like urban
30 land cover may play at least an equally critical role in cloud formation."

31
32 **12. Comments: (12) Figure3: What is this sample time series?**

33 **Answer:** Samples are collected from the pixels of the difference in cloud properties
34 that covering the four regions and randomly as shown in the Figure3.

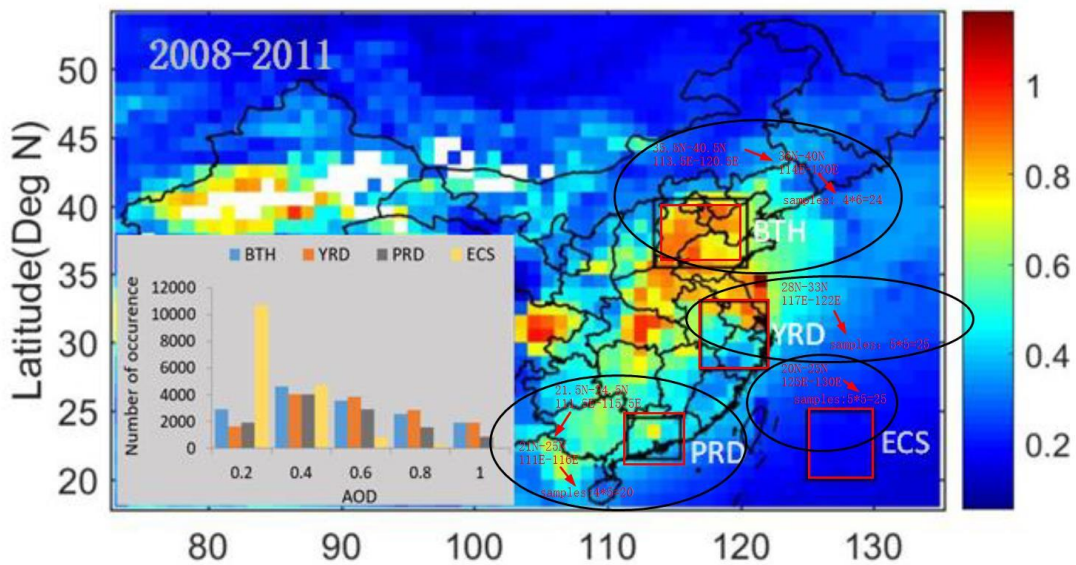

Figure A map of showing samples are collected in the four target regions.

13. Comments: (13) Page 10, Line 4: If the variation of cloud properties depends little on the initial AOD, does that not mean that section 4.3 should show no results? This would be in contrast to previous studies.

Answer: We made this change (see page 11, line 12-18 in the revised manuscript). The sentence “We can conclude that the variation of cloud properties after 3 hours depends little on the initial AOD over land, even though differences exist among the urban clusters” has been removed, which is not a correct conclusion. Further, the variation of cloud properties to the aerosol environment using different data sets (MODIS C6.1 versus older versions), we find that both COT and CWP increase over land during the 3 hours timestep for both low and high AOD. Overall, the variation in cloud properties after the timestep over BTH is less significant than over the YRD and PRD for both low and high AOD conditions. This may result from the less humid and most unstable atmospheric environments over the BTH than over the other two urban clusters (as shown in new Section 4.2). Over the ECS, in both low and high AOD conditions, CDR, CF and CTP decrease during the timestep while COT and CWP increase (see Figure 5 in the revised manuscript).

14. Comments: (14) Page 13: As there have been several previous studies looking at aerosol and cloud relationships, it would be good to set these results in context of previous work.

Answer: We made this change (see page 14 lines 8-37 and page 15 lines 1-9). The variation of cloud properties to the aerosol environment has been more clear by reanalyzing all the MODIS C6.1 data for the whole acquisition period between 2008 and 2017, rather than MODIS C5.1 data from 2008 to 2011. This issue is shown throughout the revised manuscript (all the figures were changed/modified in this respect). Following the reviewer’s comments, the results in Section 4.3 have been linked to Section 4.1 and compared to previous work.

1 Part of text in Section 4.3 was shown in follows (see page 14-15 in the revised
2 manuscript): “Figure 7 shows that the values of $d(\text{CDR})$ over the three urban clusters
3 are not mostly positive or negative, which indicates that in high AOD conditions over
4 land the variation in CDR during the three hours between the MODIS/Terra and Aqua
5 overpasses is similar. Over the ECS the values of $d(\text{CDR})$ is positive, which indicates
6 that the CDR in high AOD conditions decreases much more than during low AOD
7 conditions over ocean. Wang et al. (2014) also reported a negative correlation
8 between CDR and AOD over the ECS, in accordance with the Twomey effect.
9 Furthermore, CDR tends to be smallest in polluted and strong-inversion environments,
10 an outcome in good agreement with the findings of Matsui et al. (2006). Most of the
11 $d(\text{COT})$ values are negative over the four regions, especially for the YRD, PRD and
12 ECS. This shows that the COT increases less in high AOD conditions than in low
13 AOD conditions, over both land and ocean, which is contrast with the findings of
14 Meskhidze et al. (2009). Likewise, the values of $d(\text{CWP})$ are almost all negative over
15 the four regions although over the BTH urban cluster the values are not clear. This
16 indicates that in high AOD conditions the CWP increases less during the timestep
17 than in low AOD conditions, a result in accordance with the conclusion that higher
18 LTS is linked with a slightly lower CWP (Matsui et al., 2006). We can conclude that
19 the variation trend of COT and CWP after 3 hours depends little on the initial AOD,
20 but the initial AOD conditions can affect the amplitude of variation of COT and CWP.
21 Meanwhile, the values of $d(\text{CF})$ are smaller than zero over the ECS. This shows that
22 the cloud fraction in high AOD conditions over ECS decreases less than that in low
23 AOD conditions. However, Meskhidze et al. (2009) found that an increase of the
24 aerosol concentration may lead to enhanced reduction of afternoon cloud coverage
25 and optical thickness for marine stratocumulus regions off the coast of California,
26 Peru, and southern Africa. Therefore, the connection between AOD and variation of
27 cloud cover could be a response to regional-scale changes in aerosol covarying with
28 meteorological conditions. The value of $d(\text{CF})$ is overall positive over the PRD, which
29 indicates that over the PRD in high AOD conditions the cloud cover increases much
30 more than the cloud cover decreases in low AOD conditions. Mauger and Norris
31 (2007) have shown that scenes with large AOD and large cloud fraction experienced
32 greater LTS. As regards CTP, we find that the values of $d(\text{CTP})$ are positive over the
33 BTH and PRD urban cluster, but the values of $d(\text{CTP})$ over the other two regions are
34 not significant. It indicates that in high AOD conditions over the PRD region the CTP
35 increases much more than the CTP decreases in low AOD conditions. We can
36 conclude that the variation in $d(\text{Cloud}_X)$ is different for continental and oceanic
37 clouds. This applies to CDR, cloud fraction (CF) and CTP, but not to COT and CWP.
38 Table 2 summarizes the differences between the mean changes in cloud properties for
39 low and high AOD over the timestep of 3 hours.

40 Based on the above findings, we conclude that over the ECS the values of CDR, CWP
41 and CTP are smaller but the values of COT and CF are larger in high AOD conditions.
42 After the 3 hours timestep, CDR, CF and CTP become smaller, irrespective of the
43 AOD. Furthermore, CDR decreases much more in high AOD conditions but CF and
44 CTP decreases much more in low AOD conditions. In contrast, COT and CWP

1 become larger in both AOD conditions, more significantly in low AOD conditions.
2 Over the urban clusters, COT and CWP also increase over the timestep in both AOD
3 conditions, especially for the low AOD condition. For CF the values in low AOD
4 conditions decrease over the timestep. The CTP change behaves differently among the
5 three urban clusters during the 3 hours.”

6
7 **15. Comments: (15) Page 15, Lines 7: presumably LTS**

8 **Answer:** Yes, we made this change (see pg.16 line 7).
9

10 **16. Comments: (16) Page 15, Line 12: I read exactly the opposite, it looks like**
11 **there is a high impact of aerosol with descending air parcels.**

12 **Answer:** The effects of initial cloud fraction and meteorological conditions on the
13 change in CF under low and high AOD conditions after the 3 hours timestep over land
14 are also explored. In our new version manuscript, there are two cases are considered:
15 (1) when the cloud cover increases ($\Delta\text{Cloud}_X > 0$); (2) when the cloud cover
16 decreases ($\Delta\text{Cloud}_X < 0$). So, the results and discussions have been changed. We
17 rephrased the sentence in the revised manuscript (see page 16 lines 13-28).
18

19 **17. Comments: (17) Page 15, Line 18: Is this change a very large relative**
20 **humidity statistically significant or just noise?**

21 **Answer:** The effects of initial cloud fraction and meteorological conditions on the
22 change in CF under low and high AOD conditions after the 3 hours timestep over land
23 are also explored. In our new version manuscript, there are two cases are considered:
24 (1) when the cloud cover increases ($\Delta\text{Cloud}_X > 0$); (2) when the cloud cover
25 decreases ($\Delta\text{Cloud}_X < 0$). So, the results and discussions have been changed. We
26 rephrased the sentence in the revised manuscript (see page 17 lines 1-8).
27

28 **18. Comments: (18) Page 15, Lines 23: LTS is almost always positive**

29 **Answer:** Yes, we made this change (see page 17 lines 11-12). “A positive LTS is
30 associated with a stable atmosphere in which vertical mixing is prohibited; negative
31 PVV indicates local upward motion of air parcels.” has changed to “Low LTS
32 represents an unstable atmosphere and high LTS represents a stable atmosphere.”
33

34 **19. Comments: (19) Page 15, Line 25: 27K is a very high value for LTS and does**
35 **not distinguish much between high and low values.**

36 **Answer:** The effects of initial cloud fraction and meteorological conditions on the
37 change in CF under low and high AOD conditions after the 3 hours timestep over land
38 are also explored. In our new version manuscript, there are two cases are considered:
39 (1) when the cloud cover increases ($\Delta\text{Cloud}_X > 0$); (2) when the cloud cover
40 decreases ($\Delta\text{Cloud}_X < 0$). So, the results and discussions have been changed. We
41 rephrased the sentence in the revised manuscript (see page 17 lines 9-16).
42

43 **20. Comments: (20) Page 16, Line 4: Why is the initial cloud fraction included if**
44 **its impact is not clear? Can we learn anything from it?**

1 **Answer:** The effects of initial cloud fraction and meteorological conditions on the
2 change in CF under low and high AOD conditions after the 3 hours timestep over land
3 are also explored. In our new version manuscript, there are two cases are considered:
4 (1) when the cloud cover increases ($\Delta\text{Cloud}_X > 0$); (2) when the cloud cover
5 decreases ($\Delta\text{Cloud}_X < 0$). So, the results and discussions have been changed. We
6 rephrased the sentence in the revised manuscript (see page 17 lines 17-24).

7
8 **21. Comments: (21) Page 17, Line 28: This seems like something that could**
9 **receive more discussion.**

10 **Answer:** We rephrased the sentence in the revised manuscript (see page 20 lines
11 7-13). Text was rephrased as follows.

12 Page 20 lines 6-13: The results show that cloud cover increases much more for high
13 AOD under stronger upward motion of air parcels; Meanwhile, the increase rate of
14 cloud cover is larger for high AOD with increasing RH when RH greater than 20%.
15 With regarded to the effect of LTS on the change of cloud cover, scenes with large
16 cloud fraction variation experience large AOD and large LTS when LTS smaller
17 than 10. Conversely, scenes with smaller cloud fraction variation experience large
18 AOD and large LTS when LTS larger than 10 and smaller than 20. We also find
19 that smaller increase rate of cloud fraction occurs when scenes experience larger
20 AOD and larger initial cloud cover.

21
22 **22. Comments: (22) Page 17, Line 13: This relationship between initial cloud**
23 **fraction and changing cloud fraction is mentioned again with very little**
24 **explanation as to why.**

25 **Answer:** We made this change (see page 19 lines 28-29). Text was added as: 'Both
26 COT and CWP increase over land and ocean after the timestep, irrespective of the
27 AOD. The variation trend of COT and CWP after 3 hours depends little on the initial
28 AOD, but the initial AOD conditions can affect the amplitude of variation of COT
29 and CWP.'

19 Reply to comments on “Satellite-based estimate of the
20 variability of warm cloud properties associated with aerosol and
21 meteorological conditions”

22
23 October 30, 2018

24
25 We would like to express our appreciation to the reviewer for the detailed and
26 valuable comments which helped us a lot to improve the manuscript. Our replies to all
27 comments are shown below.

28
29 **Comments**

30 **1. Comments: (1) Page 4, Line 20: How is the possibility of vertical segregation of**
31 **cloud and aerosol accounted for? For example, the presence of a lofted aerosol**
32 **layer in the same scene as the low clouds?**

33 **Answer:** Caution is warranted in investigating the satellite-derived relations between
34 aerosol and cloud properties. With MODIS we cannot resolve the height of aerosol
35 and cloud layers, or detect aerosol above clouds. However, the physical and optical
36 properties of clouds and aerosol are quite different and these are used to separate
37 aerosols from clouds. These tests will not work for lofted aerosol layers above clouds
38 because the cloud reflectance overwhelms that of aerosols. Some other sensors rather
39 than MODIS have specific instrument characteristics that allow for this separation.

1 Firstly, as we know, CALIPSO and CloudSat can provide the height of aerosol layer
2 and cloud layer, however, the relatively low number of MODIS-CALIPSO
3 coincidences limits the further binning of the data required to investigate this issue.
4 Secondly, when it comes to the occurrence of cloud contamination in the AOD dataset,
5 this is a universal and one of the most difficult problems in aerosol retrieval. Cloud
6 detection is usually not perfect, so that undetected, or residual, clouds contaminate the
7 retrieval area which leads to AOD overestimation and in turn affects the relation
8 between aerosol and cloud properties (e.g. Sogacheva et al., 2017). A study by Mei et
9 al. (2016), comparing their MERIS cloud mask with two independent data sets, shows
10 that on the order of 70-90% of the cases are correctly classified as cloud free. This
11 result is in good agreement with that from a dedicated study on a consistency between
12 aerosol and cloud retrievals from the same instrument which showed that about 20%
13 of the pixels may be mis-classified (Klueser, 2014). In this study, the samples with
14 AOD values greater than 0.8 were excluded as a rough attempt to exclude
15 cloud-contaminated AOD to reduce the uncertainty in the observed ACI. As reported
16 by Yuan et al. (2010), the potential artefact mentioned above does not seem to be the
17 primary cause for the observed relationship between aerosol and cloud parameters.
18 Further investigations are needed to fully analyze and explain the observed
19 phenomena.

20
21 **2. Comments: (2) Section 3.2: Should this not include a sentence on how the**
22 **significance of results is to be determined? The results table speaks of statistical**
23 **significance but I'm not clear how this is measured.**

24 **Answer:** Yes, we agree. We made this change in the revised manuscript (see page 6,
25 line 21-23).

26 Page 6, line 21-23: Text was added as: 'Student's t test is used to determine whether
27 two data sets are significantly different from each other. The marker ** at the top right
28 corner of symbol "+" (or "-") denotes that the difference between a change in cloud
29 property and zero is significant (at 95% confidence level).'

30
31 **3. Comments: Section 4.1: I was under the impression from section 3.1 that the**
32 **difference in cloud properties at time=0 had been removed by re-sampling the**
33 **data. I think the relationship between sections 3.1 and 4.1 needs to be developed**
34 **with the lay reader in mind.**

35 **Answer:** Normalised histograms of cloud properties for the high and low AOD
36 populations are made for the whole region (Section 3.1), because the data volume
37 based on each 1° x 1° location is relatively small. However, the difference between
38 the cloud properties for low and high AOD at the start time is based on each 1° x 1°
39 location (Section 4.1). So the difference of the cloud properties between the low and
40 high AOD at the start time is not zero. In order to make the reader understand, text
41 was added as follows.

42 page 5 line 37-39 and page 6 lines 1-2: Text was added as: 'Note that here and in the
43 following sections, normalised histograms of cloud properties for the high and low
44 AOD populations are made for the whole region (Section 3.1), because the data

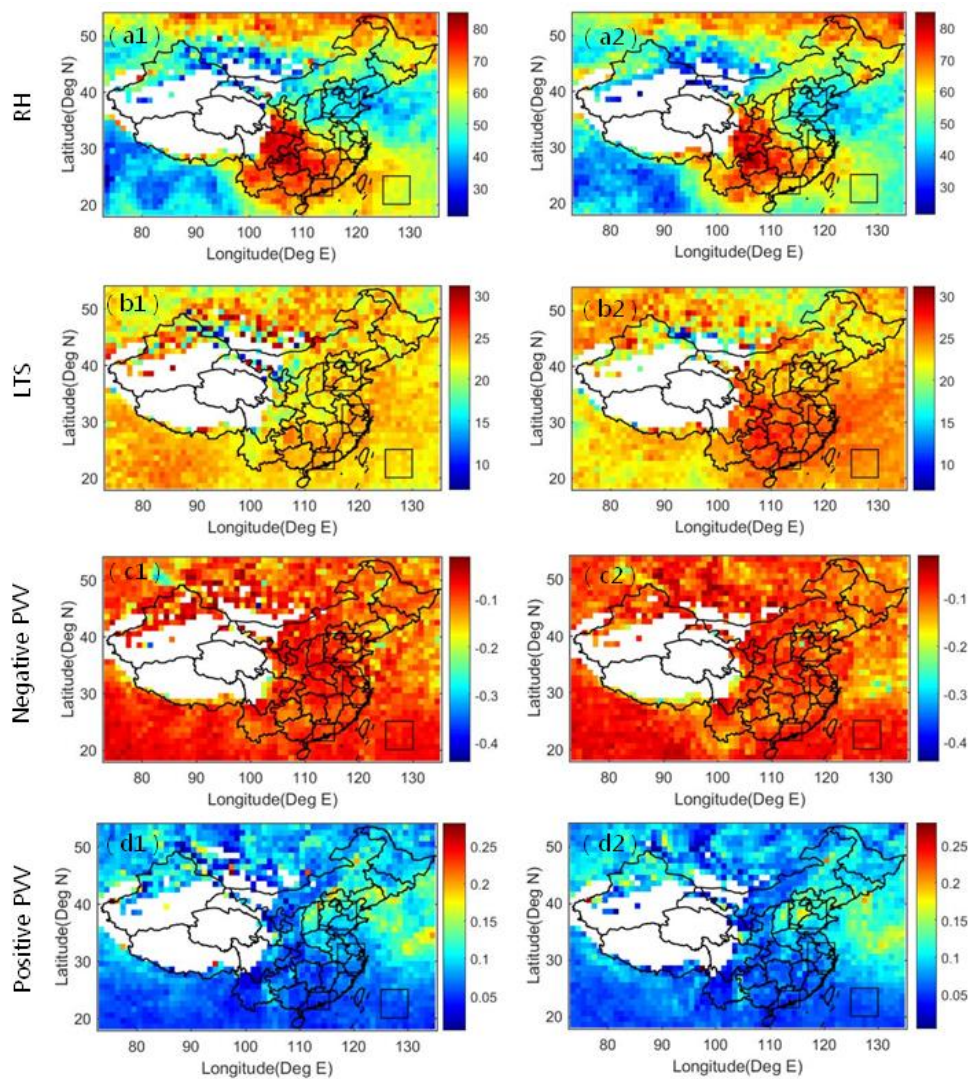

1 volume based on each $1^\circ \times 1^\circ$ location is relatively small. However, the difference
2 between the cloud properties for low and high AOD at the start time is based on each
3 $1^\circ \times 1^\circ$ location (Section 4.1). So the difference of the cloud properties between the
4 low and high AOD at the start time is not zero.'

5 Page 9, line 14-16: Text was added as: 'Although normalized histograms of
6 meteorological parameters are made for high and low AOD conditions at the start
7 time, the normalization described in Sect. 3.1 is based on the whole region.
8 Differences in meteorological conditions may still occur between each $1^\circ \times 1^\circ$ grid
9 cell.'

10 Meanwhile, in order to consider the effect of meteorological conditions on the
11 relationship between aerosol and cloud further, we analyze the meteorology of the
12 different regions in section 4.2 (see page 9-10). This new section 4.2 "The
13 meteorology of the four target regions" reads:

14 **4.2 The meteorology of the four target regions**

15 The meteorological and aerosol effects on clouds are reported to be tightly connected,
16 and this connection must be accounted for in any study of aerosol-cloud interactions
17 (Stevens and Feingold, 2009; Koren et al., 2010). Although normalized histograms of
18 meteorological parameters are made for high and low AOD conditions at the start
19 time, the normalization described in Sect. 3.1 is based on the whole region.
20 Differences in meteorological conditions may still occur between each $1^\circ \times 1^\circ$ grid
21 cell. In this study, we analyze the meteorology of the different regions, in support of
22 the interpretation of the regional variation of the relationships between aerosols and
23 clouds.

1
 2 Figure 4 Spatial distributions of meteorological parameters (top to bottom: RH, LTS, positive PVV
 3 and negative PVV) at the start time of the timestep (MODIS/Terra) for low AOD conditions (left,
 4 a1-d1) and for high AOD conditions (right, a2-d2). All the data are averaged over all years between
 5 2008 and 2017.

6 The spatial variations of the aerosol and cloud properties over the four regions,
 7 averaged over the years 2008-2017, are shown in Fig. 4. Over the urban clusters, we
 8 can see an increasing north-south pattern in RH and LTS, with the lowest values
 9 found in the PRD. For the negative PVV, the spatial distributions for the low and high
 10 AOD situations are remarkably similar, with the highest values over the BTH and
 11 decreasing toward the south to near zero over the PRD. In contrast, the positive PVV
 12 is smallest over the BTH, with little variation over the study area. Overall, the
 13 meteorological parameters over the YRD and PRD are similar to those over the ECS,
 14 irrespective of the AOD. Furthermore, the LTS is significant larger in the high AOD
 15 conditions for all the four regions. Zhao et al. (2006) proposed that the enhancement
 16 in the atmospheric stability tends to depress upward motion and precipitation, leading
 17 to an increase in aerosol particles. The spatial distributions of both positive and
 18 negative PVV in the low AOD conditions are similar to those in the high AOD
 19 conditions.

1
2 **4. Comments: Page 9, Line 31: I'm not sure what this sentence means – either**
3 **the ECS is your marine study area or it isn't. I would caution against using**
4 **parentheses in the way used in this sentence, because it is well - recognised to**
5 **make the sentence much harder to comprehend whilst reading. The writer**
6 **should be aiming to help the reader assimilate the information at normal reading**
7 **speed, not to slow them down with internal opposites that require going back**
8 **and forth over the sentence repeatedly.**

9 **Answer:** Following reviewers' comments, we use collection 6.1 data and reanalyze
10 all the data for the whole acquisition period between 2008 and 2017, rather than
11 collection 5.1 data from 2008 to 2011. As a result, the data base was expanded and
12 provides more cases. We have included this information throughout the revised
13 manuscript (all the figures were changed/modified in this respect). So, we reorganize
14 the sentences in the section (see page 11, line 16-17) and do not use parentheses in the
15 way in this sentence throughout the revised manuscript.

16 "Over the ECS, in low AOD conditions, CDR decreases during the timestep while
17 COT and CWP increase (Figure 4). For high AOD conditions, the variations of the
18 cloud properties (CDR, COT and CWP) during the timestep are similar to those for
19 low AOD conditions (Figure 5). Furthermore, it appears that COT and CWP increase
20 more at low AOD than at high AOD. Having a closer look at the CF/CTP variation in
21 both low and high conditions over ocean, we can find that CF decreases (CTP
22 increases) in low AOD conditions and CF increases (CTP decreases) in high AOD
23 conditions over ocean, albeit not over ECS. " has been changed to "Over the ECS, in
24 both low and high AOD conditions, CDR, CF and CTP decrease during the timestep
25 while COT and CWP increase (see Figure 5). " in the revised manuscript (see page
26 10). Also, as we merged section 4.2 with section 4.3 (as new Section 4.3, see pages
27 10-15), more discussion has been shown in section 4.3 of the revised manuscript (see
28 page 14-15).

29
30 **5. Comments: Page 10, Line 1: is the other "significant difference" one or two**
31 **differences? The sentence seems to suggest that CF and CTP co-vary, which in**
32 **turn suggests they need not have been studied separately.**

33 **Answer:** As mentioned above, due to the larger data set, the variation of cloud
34 properties to the aerosol environment has become more clear. This is shown
35 throughout the revised manuscript (all the figures were changed/modified in this
36 respect). We reorganized the sentences in the section (see page 11, line 19-28).

37 The paragraph "In general, the variations in cloud properties over land are similar to
38 those over ocean for both low and high AOD conditions over 3 hours. Two significant
39 differences are found between land and ocean areas. One is that CDR increases over
40 land but decreases over ocean after the timestep, another significant difference is that
41 CF decreases (CTP increases) for low AOD condition but CF increases (CTP
42 decreases) for high AOD condition over ocean after the timestep, whereas CF
43 increases (CTP decreases) for both low and high AOD conditions over land after the
44 timestep. We can conclude that the variation of cloud properties after 3 hours depends

1 little on the initial AOD over land, even though differences exist among the urban
2 clusters. The increase in afternoon cloud fraction over land is consistent with previous
3 studies concluding that continental warm clouds are likely to be well developed
4 (Wang et al., 2014; Kourtidis et al., 2015). The decrease in afternoon cloud cover over
5 ocean confirms that the largest cover for marine clouds is reached early in the
6 morning (Meskhidze et al., 2009). Table 2 summaries the differences in cloud
7 properties between the Aqua and Terra overpasses for high and low AOD conditions
8 over land and ocean during the time period 2008-2011, respectively.” **has been**
9 **changed to** “In general, the variations over 3 hours in COT and CWP over land are
10 similar to those over ocean for both low and high AOD conditions. Another
11 significant similarity is that CF decreases for low AOD conditions over land and
12 ocean during the 3h timestep. Having a closer look at the CF variation over the YRD
13 and PRD, we see that CF increases in high AOD conditions during the 3h timestep.
14 This implies that the variation of CF may depend on the initial AOD conditions. The
15 decrease in afternoon cloud cover over ocean confirms that the largest cover for
16 marine clouds is reached early in the morning as was also concluded by Meskhidze et
17 al. (2009). Meanwhile, a significant difference is found between land and ocean areas,
18 i.e. in high AOD conditions CDR increases over land but decreases over ocean during
19 the 3h timestep. Table 2 summaries the differences in cloud properties between the
20 Aqua and Terra overpasses for high and low AOD conditions over land and ocean
21 during the time period 2008-2017.”

22
23 **6. Comments: Figures 3-5: might it be possible to shade the graphs on the**
24 **right-hand columns of these figures to show when changes are self-consistent**
25 **from a microphysics or cloud dynamics point of view?**

26 **Answer:** We do not understand what the reviewer means with “self-consistent from a
27 micro-physics or cloud dynamics point of view”. Hence, we have not added a shading
28 to these graphs.

29
30 **7. Comments: Section 4.3 and Figure 6: This reader is left feeling that there is**
31 **very little added value in this section. The statistics all look close to zero and**
32 **noisy and the text doesn’t make any very strong statements over and above those**
33 **from previous sections. Is this section really necessary?**

34 **Answer:** As mentioned above, in response to the reviewers’ comments, we use
35 collection 6.1 data and reanalyze all the data for the whole acquisition period between
36 2008 and 2017, rather than collection 5.1 data from 2008 to 2011. Therefore, the
37 variation of cloud properties to the aerosol environment has become more clear. This
38 is explained throughout the revised manuscript (all the figures were changed/modified
39 in this respect). Furthermore, Section 4.2 was merged with section 4.3 (as new
40 Section 4.3, see pages 10-15), explicitly examining the difference of cloud properties
41 in relation to aerosol environment. Also a new Section 4.2 was added (see response to
42 question 3) to describe the meteorology of the four target regions, in support of the
43 interpretation of the regional variation of relationship between aerosol and cloud (see
44 page 9-10).

8. Comments: Section 4.4 is too definitive considering the uncertainty shown in Figure 7. I also missed a tie-back to basic cloud physics – how is the reader to interpret the effect of aerosol concentration on cloud parameters when the air is descending and cloud formation therefore suppressed? Some context is required here to help the reader who is not familiar with such analyses.

Answer: Yes, we made this change (see page 16 lines 13-16). “The presence of upward motion, as indicated by negative PVV, can enhance the interaction between aerosol particles and clouds as it makes the ambient environment favorable for cloud formation, and vice versa (Jones et al., 2009).” has been changed to “The presence of upward motion, as indicated by negative PVV, can enhance the interaction between aerosol particles and clouds as it promotes vertical mixing of the aerosol particles and thus reach the cloud condensation level where they grow into cloud droplets (Jones et al., 2009).” As the variation of cloud properties to the aerosol environment has become more clear, we also reorganized the sentences in the Section 4.4 (see pages 16-17).

Minor comments

1. Comments: (1) Page 2, line 36: delete ‘desperately’

Answer: Yes, we made this change (see page 3, line 1).

2. Comments: (2) Page 6, Figure 2: would plotting on log axes help the differences to be visible? For the caption: presumably this is an example of a PDF of CF?

Answer: We use collection 6.1 data and reanalyze all the data for the whole acquisition period between 2008 and 2017, rather than collection 5.1 data from 2008 to 2011. So, Figure 2 has also been changed and the differences can be seen easily (see page 6).

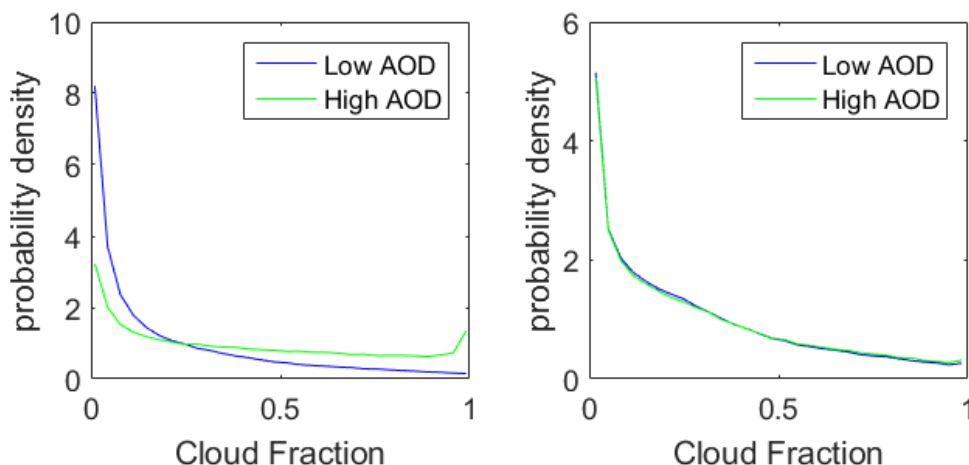

Figure 2. An example of the probability density distribution of warm cloud fraction (CF) for low and high AOD conditions. (a) there is a strong link between AOD and CF before histogram normalization, (b) the link is reduced after histogram normalization.

1 **3. Comments: (3) Page 6, line 12: “Cloud_X (where X=CF, COT, CWP, CDR or**
2 **CTP)” – just for extra clarity.**

3 **Answer: Yes, we made this change (see page 6, line 11).**
4

5 **4. Comments: (4) Page 6, line 13-16: “_Cloud_X[High AOD]” should be**
6 **overbarred in text as in equation.**

7 **Answer: Yes, we made this change (see page 6, line 12).**
8

9 **5. Comments: (5) Page 9, line 27: plot should be plotted.**

10 **Answer: We use collection 6.1 data and reanalyze all the data for the whole**
11 **acquisition period between 2008 and 2017, rather than collection 5.1 data from 2008**
12 **to 2011. So, Figure 4 and 5 have been changed to Figure 5 and 6 (see page 12-13).**
13

14 **6. Comments: (6) Page 15, line 12: “when PVV is positive” is more consistent.**

15 **Answer: Because the analyzed dataset was different (MODIS C6.1 versus older**
16 **versions), the result also changed. We rephrased the sentence in the revised**
17 **manuscript (see page 16).**
18

19 **7. Comments: (7) Page 17, line 1: the statistical methods are not described**
20 **anywhere that I can see.**

21 **Answer: Page 19, lines 8-9: ‘Data over these four study areas were collected for the**
22 **years 2008 to 2017, and analyzed using statistical methods.’ was changed to ‘ Data**
23 **over these four study areas were collected for the years 2008 to 2017 and analyzed in**
24 **statistical sense.’ Here, we mean with statistical sense that we looked at the 10-year**
25 **mean properties rather than at individual case studies.**
