The authors used SP2 and VTDMA techniques to determine the mixing state of rBC and showed a number of interesting and important results for BC particles in the NCP region. I have a short comment.

For the size inversion by SP2 and the interpretation of internally-mixed BC particles, the authors made an important assumption that internally-mixed BC has a concentric core-shell structure, where the Mie theory can be applied. However, a number of recent studies (e.g., He et al., 2015, 2016; China et al., 2015) have shown that non-core-shell

Discussion paper

structures of coated/aged BC particles are ubiquitous and could significantly affect BC optical properties. Therefore, assuming a core-shell structure may introduce some uncertainties. It would be useful if the authors could include these recent references and add some discussions on this aspect.
