

To Dr Sally Pusede:

Thanks so much for your careful checking of all our detailed revisions to the previous manuscript. We have again fully revised the manuscript according to your comments and conducted a thorough proofreading from authors and an editor. Thanks again for processing our manuscript and giving so many valuable comments.

Line 286: write out meanRHU and maxWIN. Write out other instances as well.

R: Sorry for these abbreviations. We have corrected them all in the revised manuscript.

The organization with letter labeling (a, b, c.) should be changed to better adhere to ACP style conventions.

R: Thanks so much for pointing this out. We have checked many newly published ACP papers and realized that the labeling (1,2,3) at the beginning is a more frequently used style in ACP. So we have adjusted the labeling in the revised manuscript.–

I appreciate the quantitative results added to the Results section. The section is now quite long, I recommend either removing rho values inessential to the main points, or adding a table to display the values to improve readability.

R: Thanks so much for this. We also realized that some quantitative description is too long and prevented readers having a clear understanding of given information. Therefore, we have removed much of the quantitative text in the result part and added two tables to the revised manuscript as follows:

Table 1 Major meteorological influencing factors for PM_{2.5} concentrations in four mega cities within different regions

City	Season	Three major meteorological factors		
Beijing	Spring	Humidity (0.48)	Wind (0.37)	Evaporation (0.31)
	Summer	Humidity (0.39)	Temperature (0.34)	SSD (0.25)
	Autumn	Humidity (0.56)	Evaporation (0.51)	Wind (0.41)
	Winter	Humidity (0.76)	Wind (0.57)	Evaporation (0.52)
Shanghai	Spring	Temperature (0.264)	air pressure (0.260)	Wind (0.25)
	Summer	Temperature (0.40)	Wind (0.38)	Humidity (0.27)
	Autumn	Temperature (0.39)	Wind (0.28)	Humidity (0.17)
	Winter	Precipitation (0.36)	Wind direction (0.25)	Humidity (0.19)
Wuhan	Spring	Precipitation (0.18)	Wind (0.16)	Temperature (0.09)
	Summer	Humidity (0.47)	Temperature (0.41)	Wind (0.34)
	Autumn	Wind (0.44)	Precipitation (0.31)	Temperature (0.26)
	Winter	Precipitation (0.33)	Temperature (0.19)	Wind (0.15)
Guangzhou	Spring	Wind (0.31)	Precipitation (0.24)	Air pressure (0.23)
	Summer	Air pressure (0.51)	Temperature (0.41)	Wind (0.37)
	Autumn	Temperature (0.47)	Wind (0.36)	Precipitation (0.29)
	Winter	Temperature (0.52)	Wind (0.48)	Air pressure (0.33)

Table 2 Summer and winter major influencing meteorological factors for PM_{2.5} concentrations in four major cities in the North China region

City	Season	Major influencing meteorological factors			
Beijing	Summer	humidity	temperature	SSD	
		0.39	0.34	0.25	
Beijing	Winter	humidity	wind	evaporation	SSD
		0.76	0.57	0.52	0.50
Tianjin	Summer	precipitation	air pressure	temperature	
		0.34	0.25	0.22	
Tianjin	Winter	humidity	wind	evaporation	SSD
		0.56	0.50	0.44	0.41
Shijiazhuang	Summer	SSD	humidity	evaporation	
		0.4	0.26	0.26	
Shijiazhuang	Winter	SSD	wind	evaporation	humidity
		0.62	0.60	0.58	0.56
Taiyuan	Summer	temperature	air pressure	precipitation	
		0.32	0.23	0.20	
Taiyuan	Winter	humidity	SSD	wind	
		0.61	0.44	0.41	

Is Fig. 4 necessary? it appears to provide the same information as Table 1.

R: Yes, some important information (mean value, SD) can be seen from Table 3(Table 1 in the original manuscript). But the violin Chart (Fig 4) additionally provides some additional information of the influence of individual meteorological influence. The most important information from the Figure, which cannot be understood from the table, is the frequency of different p values amongst 188 cities (similar to, but better than a histogram). This important information can help readers have a better understanding of the distribution of the influence of meteorological factors on PM_{2.5} concentrations across China. Therefore, we would appreciate that you could understand we prefer to keep this figure to give readers a comprehensive understanding of the statistical distribution of

meteorological influences on PM_{2.5} concentrations across China.

The manuscript would benefit from a thorough proofreading.

R: A Thorough proofreading has been conducted by authors and expert editor.

Line 539: PM_{2.5}

R: Corrected.

I recommend the Discussion section be edited to be made slightly more concise, if possible.

R: This is a very good point. After a careful check of the discussion part, we have deleted many redundant sentences and made the discussion more concise. Thanks so much for this valuable comment.

13 **Abstract**

14 With frequent air pollution episodes in China, growing research emphasis has been put on
15 quantifying meteorological influences on PM_{2.5} concentrations. However, these studies
16 mainly focus on isolated cities whilst meteorological influences on PM_{2.5} concentrations at
17 the national scale have yet been examined comprehensively. This research employs the CCM
18 (Cross Convergent Mapping) method to understand the influence of individual meteorological
19 factors on local PM_{2.5} concentrations in 188 monitoring cities across China. Results indicate
20 that meteorological influences on PM_{2.5} concentrations are of notable seasonal and regional
21 variations. For the heavily polluted North China region, when PM_{2.5} concentrations are high,
22 meteorological influences on PM_{2.5} concentrations are strong. The dominant meteorological
23 influence for PM_{2.5} concentrations varies across locations and demonstrates regional
24 similarities. For the most polluted winter, the dominant meteorological driver for local PM_{2.5}
25 concentrations is mainly the wind within the North China region whilst precipitation is the
26 dominant meteorological influence for most coastal regions. At the national scale, the
27 influence of temperature, humidity and wind on PM_{2.5} concentrations is much larger than that
28 of other meteorological factors. Amongst eight factors, temperature exerts the strongest and
29 most stable influence on national PM_{2.5} concentrations in all seasons. Due to notable temporal
30 and spatial differences in meteorological influences on local PM_{2.5} concentrations, this
31 research suggests pertinent environmental projects for air quality improvement should be
32 designed accordingly for specific regions.

34 **Introduction**

35 With rapid social and economic growth in China, both the government and residents are
36 placing more and more emphasis on the sustainability of the ambient environment, and
37 air quality has become one of the most concerned social and ecological issues. [Since](#)
38 ~~2013~~[Recently](#), the frequency of air pollution episodes with high PM_{2.5} concentrations
39 and the number of cities influenced by PM_{2.5} pollution have increased notably in China
40 ~~since 2013~~. Statistical records from the national air quality publishing platform
41 (<http://113.108.142.147:20035/emcpublish/>) revealed that PM_{2.5} induced pollution
42 ~~episodesevents~~ occurred in 25 provinces and more than 100 middle-large cities whilst
43 there were on average 30 days with hazardous PM_{2.5} concentrations for each monitoring
44 city in 2014.

45 High PM_{2.5} concentrations not only influence people's daily life (e.g. high PM_{2.5}
46 concentrations caused severe traffic jam), but also severely threaten the health of
47 residents that suffer from polluted air quality. Recent studies have suggested that
48 airborne pollutants, PM_{2.5} in particular, are closely related to cardiovascular
49 disease-related mortality (Garrett and Casimiro, 2011, Li et al., 2015a; Lanzinger et al.,
50 2015), emergency room visits (Qiao et al., 2014) and all year non-accidental mortality
51 (Pasca et al., 2014). Due to its strong negative influences on public health, scholars have
52 been working towards a better understanding of sources (Guo et al., 2012; Zhang et al.,
53 2013; Gu et al., 2014; Liu et al., 2014; Cao et al., 2014), characteristics (Wei et al., 2012;
54 Zhang et al., 2013; Hu et al., 2015; Zhang, F. et al., 2015; Zhen et al., 2016; Zhang et al.,
55 2016) and seasonal variations (Cao et al., 2012; Shen et al., 2014; Yang and Christakos,
56 2015; Wang et al., 2015; Chen et al., 2015; Chen, Y. et al. 2016; Chen, Z. et al., 2016) of
57 ~~PM_{2.5} and other airborne pollutants~~. Meanwhile, large-scale research on the variation and
58 distribution of PM_{2.5} [concentrations](#) has been conducted using a variety of remote
59 sensing sources and spatial data analysis methods (Ma et al., 2014; Kong et al., 2016).

60 One key issue for air quality research is to find the source and influencing factors for
61 airborne pollutants. Although quantitative contributions of different sources (e.g. coal
62 burning and automobile exhaust) to airborne pollutants remain controversial,
63 meteorological influences on airborne pollutants have been examined in depth by more
64 and more scholars. Recent studies conducted in different countries indicated that PM_{2.5}
65 [concentrations](#) were closely related to temperature (Pearce et al., 2011; Yadav et al., 2014;

66 Grundstrom et al., 2015), wind speed (Galindo et al., 2011; El-Metwally and Alfaro,
67 2013; Yadav et al., 2014) and precipitation (Yadav et al., 2014). Meanwhile,
68 meteorological influences on PM_{2.5} concentrations across China have also become a hot
69 research topic. Yao (2017) revealed a generally negative correlation between evaporation
70 and PM_{2.5} concentrations in a series of cities within the North China plain. Huang et al.
71 (2015) and Yin et al., (2016) found a negative influence of sunshine duration and a
72 positive influence of relative humidity on PM_{2.5} concentrations in Beijing. Li et al. (2015)
73 suggested that air pressure and temperature [were](#) positively correlated with PM_{2.5}
74 concentrations in Chengdu. For Nanjing (Chen, T. et al, 2016) and Hong Kong (Fung et
75 al., 2014), precipitation exerted a strong influence on PM_{2.5} concentrations in winter,
76 when the influence of wind speed on PM_{2.5} concentrations was weak. Meanwhile,
77 wind speed exerted a major influence on PM_{2.5} concentrations in Beijing in winter.
78 Through experiments, Guo (et al, 2016) found that the influence of precipitation on
79 PM_{2.5} concentrations in Xi'an was weaker than that in Guangzhou. Zhang et al. (2015b)
80 quantified the correlations between meteorological factors and main airborne pollutants
81 in three megacities, Beijing, Shanghai and Guangzhou, and pointed out that the
82 influences of meteorological factors on the formation and concentrations of [airborne](#)
83 [pollutants](#)PM_{2.5} varied significantly across seasons and geographical locations. Chen, Z.
84 et al. (2017) quantified the meteorological influences on local PM_{2.5} concentrations in the
85 Beijing-Tianjin-Hebei region and revealed that wind, humidity and solar radiation were
86 major meteorological factors that significantly influenced local PM_{2.5} concentrations in
87 winter. These studies revealed the correlations between PM_{2.5} concentrations and a
88 diversity of meteorological factors in some specific cities. However, findings from these
89 studies conducted at a local scale cannot reveal regional and national patterns of
90 meteorological influences on PM_{2.5} concentrations in China. In addition, these studies
91 mainly employed short-term observation data (e.g. one season or one year) and thus
92 revealed characteristics of meteorological influences on PM_{2.5} concentrations may be
93 biased by inter-annual variations.

94 Due to the diversity of meteorological factors and complicated interactions between
95 them, Pearce et al (2011) suggested that multiple models and methods should be
96 comprehensively employed to quantify the influence of meteorological factors on local
97 airborne pollutants. [For](#) complicated interactions between different factors, Sugihara et al.

98 (2012) suggested that correlation analysis between two variables in a complicated
99 ecosystem might lead to mirage correlations and the extracted correlation coefficient
100 between two variables could be influenced significantly by other variables in the
101 ~~ecosystem.~~ ~~ecosystem.~~ ~~Therefore,~~ Sugihara et al. (2012) proposed a CCM (Cross
102 Convergent Mapping) method to qualify the bi-direction coupling between two variables
103 without the influence from other variables. The CCM method can effectively remove
104 mirage correlations and extract reliable causality between two variables. Our previous
105 research (Chen, Z., 2017) found that the CCM method performed better in quantifying
106 the influence of individual meteorological factors on PM_{2.5} concentrations than
107 traditional correlation analysis through comprehensive comparison. However, this study
108 mainly focused on the meteorological influences on PM_{2.5} concentrations in a specific
109 region. As pointed out by some scholars [\(He et al., 2017\)](#), interactions between
110 meteorological factors and airborne pollutants are of great variations [across](#) different
111 ~~regions, yet most relevant studies have been conducted at the local or regional scale.~~
112 China is a large country, including many regions with completely different air pollution
113 levels, geographical conditions and meteorological types. To better understand the
114 variations of meteorological influences on PM_{2.5} concentrations, a comparative study at
115 the national scale is required.

116 According to these challenges, this research aims to analyze and compare the influence
117 of individual meteorological factors on PM_{2.5} concentrations across China. Based on
118 the CCM causality analysis, we quantified the influence of eight meteorological factors
119 on PM_{2.5} concentrations in 188 monitoring cities across China using the observation data
120 from March, 2014 to February, 2017. To comprehensively understand the
121 spatio-temporal patterns of meteorological influences on PM_{2.5} concentrations across
122 China, we a). investigated comprehensive meteorological influences on PM_{2.5}
123 concentrations in 37 regional representative cities, b) extracted the seasonal dominant
124 meteorological factor for each monitoring city, and c) conducted a comparative statistics
125 of the influence of different meteorological factors on PM_{2.5} concentrations at the
126 national scale.

127 **2 Materials**

128 **2.1 Data sources**

129 **2.1.1 PM_{2.5} data**

130 PM_{2.5} data are acquired from the website PM25.in. This website collects official data of
131 PM_{2.5} concentrations provided by China National Environmental Monitoring Center
132 (CNEMC) and publishes hourly air quality information for all monitoring cities. Before
133 Jan 1st, 2015, PM25.in publishes data of 190 monitoring cities. Since Jan 1st, 2015, the
134 number of monitoring cities has increased to 367. By calling specific API (Application
135 Programming Interface) provided by PM25.in, we collect hourly PM_{2.5} data for target
136 cities. The daily PM_{2.5} concentrations for each city is calculated using the averaged value
137 of hourly PM_{2.5} concentrations measured at all available local observation stations. For a
138 consecutive division of different seasons and multiple-year analysis, we collected PM_{2.5}
139 data from March 1st, 2014 to February 28th, 2017 for the following analysis.

140 **2.1.2 Meteorological data**

141 The meteorological data for these monitoring cities are obtained from the “China
142 Meteorological Data Sharing Service System”, part of National Science and Technology
143 Infrastructure. The meteorological data are collected through thousands of observation
144 stations across China. Previous studies (Zhang et al., 2015b; Pearce et al., 2011; Yadav et
145 al., 2014) revealed that such meteorological factors as relative humidity, temperature,
146 wind speed, wind direction, solar radiation, evaporation, precipitation, and air pressure
147 might be related to PM_{2.5} concentrations. Therefore, to comprehensively understand
148 meteorological driving forces for PM_{2.5} concentrations in China, all these potential
149 meteorological factors were selected as candidate factors. To better quantify the role of
150 ~~these individual~~ meteorological factors in affecting local PM_{2.5} concentrations, these
151 factors are further categorized into some sub-factors: evaporation (small evaporation and
152 large evaporation), temperature (daily max temperature, mean temperature, minimum
153 temperature, and largest temperature difference for the day), precipitation (total
154 precipitation from 8am-8pm, total precipitation from 8pm-8am and total precipitation for
155 the day), air pressure (daily max pressure, mean pressure and minimum pressure),
156 humidity (daily mean and minimum relative humidity), radiation (sunshine duration for

带格式的: 上标

157 the day, short for SSD), wind speed (mean wind speed, max wind speed and extreme
158 wind speed), wind direction (max wind direction for the day). Some meteorological
159 factors are briefly explained here. Evaporation indicates the amount of
160 evaporation-induced water loss during a certain period and is usually calculated using the
161 depth of evaporated water in a container. For this research, small (large) evaporation
162 indicates the amount of evaporated water measured using a container with a diameter of
163 10cm (30cm) during 24 hours (unit: mm). Generally, the measured values using the two
164 types of equipment are of slight differences. SSD represents the hours of sunshine
165 measured during a day for a specific location on earth. The max wind speed indicates
166 the max mean wind speed during any 10 minutes within a day's time. The extreme
167 wind speed indicates the max instant (for 1s) wind speed within a day's time. The
168 max wind direction indicates the dominant wind direction for the period with the
169 max wind speed. As there are one or more observation stations for each city, the daily
170 value for each meteorological factor for each city was calculated using the mean value of
171 all available observation stations within the target city. To conduct time series
172 comparison, we also collected meteorological data from March 1st, 2014 to February 28th,
173 2017.

174 **2.2 Study sites**

175 For a comprehensive understanding of meteorological influences on local PM_{2.5}
176 concentrations across China, all monitoring cities (except for Liaocheng and Zhuji,
177 where continuous valid meteorological data were not available) during the study period
178 were selected for this research. The 188 cities included most major cities (Beijing,
179 Shanghai, Guangzhou, etc.) in China. For regions (e.g. Beijing-Tianjin-Hebei region)
180 with heavy air pollution, the density of monitored cities was much higher than that in
181 regions with good air quality.

182 **3 Methods**

183 Due to complicated interactions in the atmospheric environment, it is highly difficult to
184 quantify the causality of individual meteorological factors on PM_{2.5} concentrations
185 through correlation analysis. Instead, a robust causality analysis method is required.

186 To extract the coupling between individual variables in complex systems, Sugihara et al.
187 (2012) proposed a convergent cross mapping (CCM) method. Different from Granger

188 causality (GC) analysis (Granger, 1980), the CCM method is sensitive to weak to
 189 moderate coupling in ecological time series. By analyzing the temporal variations of two
 190 time-series variables, their bidirectional coupling can be featured with a convergent map.
 191 If the influence of one variable on the other variable is presented as a convergent curve
 192 with increasing time series length, then the causality is detected; If the curve
 193 demonstrates no convergent trend, then no causality exists. The predictive skill (defined
 194 as ρ value), which ranges from 0 to 1, suggests the quantitative causality of one
 195 variable on the other.

196 The principle of CCM algorithms is briefly explained as follows (Luo et al. 2014). Two
 197 time series $\{X\} = [X(1), \dots, X(L)]$ and $\{Y\} = [Y(1), \dots, Y(L)]$ are defined as the temporal
 198 variations of two variables X and Y . For $r = S$ to L ($S < L$), two partial time series
 199 $[X(1), \dots, X(L_P)]$ and $[Y(1), \dots, Y(L_P)]$ are extracted from the original time series (r is the
 200 current position whilst S is the start position in the time series). Following this, the
 201 shadow manifold M_X is generated from $\{X\}$, which is a set of lagged-coordinate vectors
 202 $x(t) = \langle X(t), X(t-\tau), \dots, X(t-(E-1)\tau) \rangle$ for $t = 1+(E-1)\tau$ to $t = r$. To generate a
 203 cross-mapped estimate of $Y(t)$ ($\hat{Y}(t)|M_X$), the contemporaneous lagged-coordinate vector
 204 on M_X , $x(t)$ is located, and then its $E+1$ nearest neighbors are extracted, where $E+1$ is the
 205 minimum number of points required for a bounding simplex in an E -dimensional space
 206 (Sugihara and May, 1990). Next, the time index of the $E+1$ nearest neighbors of $x(t)$ is
 207 denoted as t_1, \dots, t_{E+1} . These time index are used to identify neighbor points in Y and then
 208 estimate $Y(t)$ according to a locally weighted mean of $E+1$ $Y(t_i)$ values (Equation 1).

$$209 \quad \hat{Y}(t)|M_X = \sum_{i=1}^{E+1} w_i Y(t_i) \quad (E1)$$

210 Where w_i is a weight calculated according to the distance between $X(t)$ and its i^{th} nearest
 211 neighbor on M_X . $Y(t_i)$ are contemporaneous values of Y . The weight w_i is determined according to
 212 Equation 2.

$$213 \quad w_i = u_i / \sum_{j=1}^{E+1} u_j \quad (E2)$$

214 Where $u_i = e^{-d[x(t), x(t_i)]/d[x(t), x(t_i)]}$ whilst $d[x(t), x(t_i)]$ represents the Euclidean distance between
 215 two vectors.

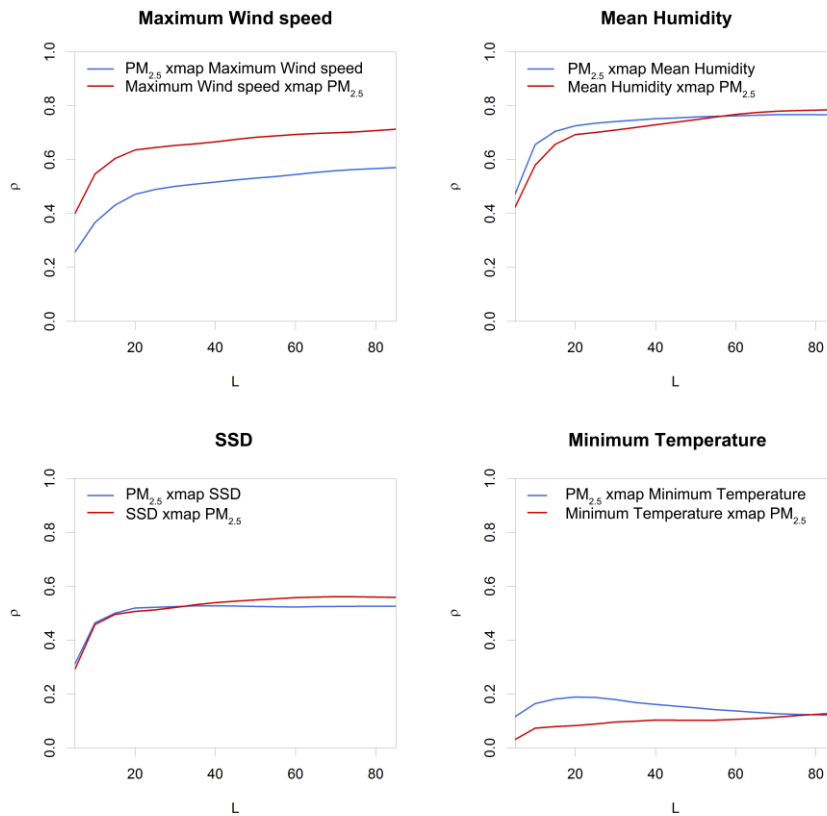

216 In our previous research, interactions between the air quality in neighboring cities (Chen,

217 Z. et al., 2016), and bidirectional coupling between individual meteorological factors and
218 PM_{2.5} concentrations (Chen, Z. et al., 2017) were quantified effectively using the CCM
219 method. By comparing the performance of correlation analysis and CCM method, Chen,
220 Z. et al. (2017) suggested that correlation analysis ~~may~~ might lead to a diversity of biases
221 due to complicated interactions between individual meteorological factors. Firstly, some
222 mirage correlations (two variables with a moderate correlation coefficient) extracted
223 using the correlation analysis were revealed effectively using the CCM method (the ρ
224 value between two variables was 0). Secondly, some weak coupling, which was hardly
225 detected using the correlation analysis (the correlation between the two variables were
226 not significant), was extracted using the CCM method (a small ρ value). Meanwhile,
227 as Sugihara et al. (2012) suggested, the correlation between two variables could be
228 influenced significantly by other agent variables and thus the value of correlation
229 coefficient between two variables could not reflect the actual causality between them.
230 Chen et al. (2017) further revealed that the correlation coefficient between individual
231 meteorological factors and PM_{2.5} concentrations was usually much larger than the ρ
232 value. This indicated that the causality of individual meteorological factors on PM_{2.5}
233 concentrations was generally overestimated using the correlation analysis, due to the
234 influences from other meteorological factors. In this case, the CCM method is an
235 appropriate tool for quantifying bidirectional interactions between PM_{2.5} concentrations
236 and individual meteorological factors in complicated atmospheric environment.

237 **4 Results**

238 Seasonal variations of PM_{2.5} concentrations have been revealed in Beijing (Chen et al.,
239 2015; Chen, Y. et al., 2016; Chen, Z. et al., 2016), Nanjing (Shen et al., 2014), Shandong
240 Province (Yang and Christakos, 2015) and the Beijing-Tianjin-Hebei region (Wang et al.
241 2015; Chen, Z. et al., 2017). In addition to these local and regional studies, Cao et al.
242 (2012) further compared seasonal variations of PM_{2.5} concentrations in seven southern
243 cities (Chongqing, Guangzhou, Hong Kong, Hangzhou, Shanghai, Wuhan, and Xiamen)
244 and seven northern cities (Beijing, Changchun, Jinchang, Qingdao, Tianjin, Xi'an, and
245 Yulin) across China. Hence, the research period was divided into four seasons.
246 According to traditional season division for China, spring was set as the period between
247 March 1st, 2014 and May 31st, 2014; summer was set as the period between June 1st,
248 2014 and August 31st, 2014; autumn was set as the period between September 1st, 2014

249 and November 30th, 2014; and winter was set as the period between December 1st, 2014
250 and February 28th, 2015. For each city, the bidirectional coupling between individual
251 meteorological factors and PM_{2.5} concentrations in different seasons was analyzed
252 respectively using the CCM method. The CCM method is highly automatic and only few
253 parameters need to be set for running this algorithm: E (number of dimensions for the
254 attractor reconstruction), τ (time lag) and b (number of nearest neighbors to use for
255 prediction). The value of E can be 2 or 3. A larger value of E produces more accurate
256 convergent maps. The variable b is decided by E ($b = E + 1$). A small value of τ leads
257 to a fine-resolution convergent map, yet requires much more processing time. Through
258 experiments, we found that the final results were not sensitive to the selection of
259 parameters and different parameters mainly exerted influences on the presentation effects
260 of CCM. In this research, to acquire optimal interpretation effects of convergent cross
261 maps, the value of τ was set as 2 days and the value of E was set 3. For each
262 meteorological factor, its causality coupling with PM_{2.5} concentrations can be
263 represented using a convergent map. Since it is not feasible to present all these
264 convergent maps here, we simply display some exemplary maps to demonstrate how
265 CCM works (Fig 1). As a heavily polluted city, we presented the interactions between
266 PM_{2.5} concentrations and meteorological factors in Beijing in winter, when the local
267 PM_{2.5} concentration was the highest, as an example. Four major meteorological factors,
268 wind, humidity, radiation and temperature, which exerted much stronger influences on
269 PM_{2.5} concentrations than other factors, were employed. Due to the strong bidirectional
270 coupling between PM_{2.5} concentrations and these meteorological factors, Figure 1 not
271 only demonstrates how CCM output could be interpreted, but also provides readers with
272 a general comparison of the magnitude of simultaneous influences of different
273 meteorological factors on the local PM_{2.5} concentration and its feedback effects.

274

 276 **meteorological factors and $PM_{2.5}$ concentrations in Beijing (2014, winter)**
 277 ρ : predictive skills. L : the length of time series. A xmap B stands for convergent cross mapping B
 278 from A, in other words, the causality of variable B on A. For instance, $PM_{2.5}$ xmap meanRHU-mean
 279 humidity stands for the causality of meanRHU-mean humidity on $PM_{2.5}$ concentrations. meanRHU
 280 mean humidity xmap $PM_{2.5}$ stands for the feedback effect of $PM_{2.5}$ concentrations on mean humidity.
 281 ρ indicates the predictive skills of using mean humidityRHU to retrieve $PM_{2.5}$ concentrations.
 282 According to Fig 1, one can see that the quantitative influence of individual
 283 meteorological factors on $PM_{2.5}$ was well extracted using the CCM method whilst the
 284 feedback effect of $PM_{2.5}$ on specific meteorological factors was revealed as well. For
 285 Beijing, mean RHU-humidity and maxWIN-maximum wind speed exerted a strong
 286 influence on local $PM_{2.5}$ concentrations in Winter-winter ($\rho > 0.4$) whilst SSD and
 287 minimum temperature #TEM also had a weaker influence on local $PM_{2.5}$ concentrations.

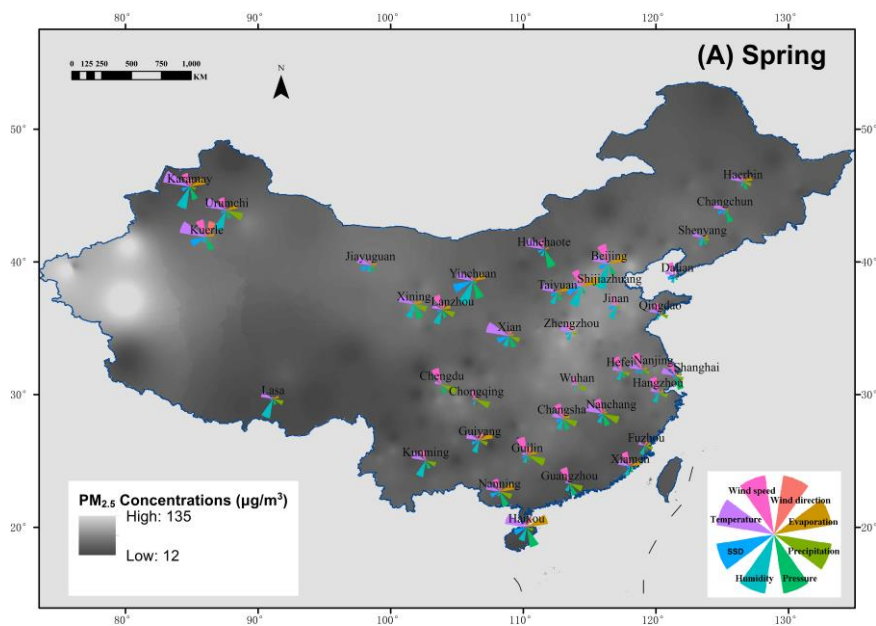

288 (ρ close to 0.2). On the other hand, high $PM_{2.5}$ concentrations had an even stronger
289 feedback influence on [mean humidity](#)~~meanRHU~~, [maximum wind speed](#)~~maxWIN~~ and
290 SSD (ρ close to 0.6) whilst $PM_{2.5}$ had little influence on ~~minTEM~~ [minimum](#)
291 [temperature](#) (ρ close to 0). The bidirectional coupling between $PM_{2.5}$ concentrations and
292 individual meteorological factors provides useful reference for a better understanding of
293 the form and development of $PM_{2.5}$ -induced air pollution episodes. For Beijing, low
294 wind speed (high humidity and low SSD) in winter results in high $PM_{2.5}$ concentrations,
295 which in turn causes lower wind speed (higher humidity and lower SSD). In
296 consequence, $PM_{2.5}$ concentrations are increased further by the changing wind (humidity
297 and SSD) situation. This mechanism causes a quickly rising $PM_{2.5}$ concentrations, which
298 brings the atmospheric environment to a comparatively stable status. In this case,
299 persistent high-concentration $PM_{2.5}$ is unlikely to disperse and usually lasts for a long
300 period in this region. Similarly, bidirectional interactions between $PM_{2.5}$ concentrations
301 and other meteorological factors can as well be quantified using the CCM method. Since
302 the main aim of this research is to understand the influence of individual meteorological
303 factors on $PM_{2.5}$ concentrations across China, the feedback effect of $PM_{2.5}$ concentrations
304 on specific meteorological factors is not explained in details herein.

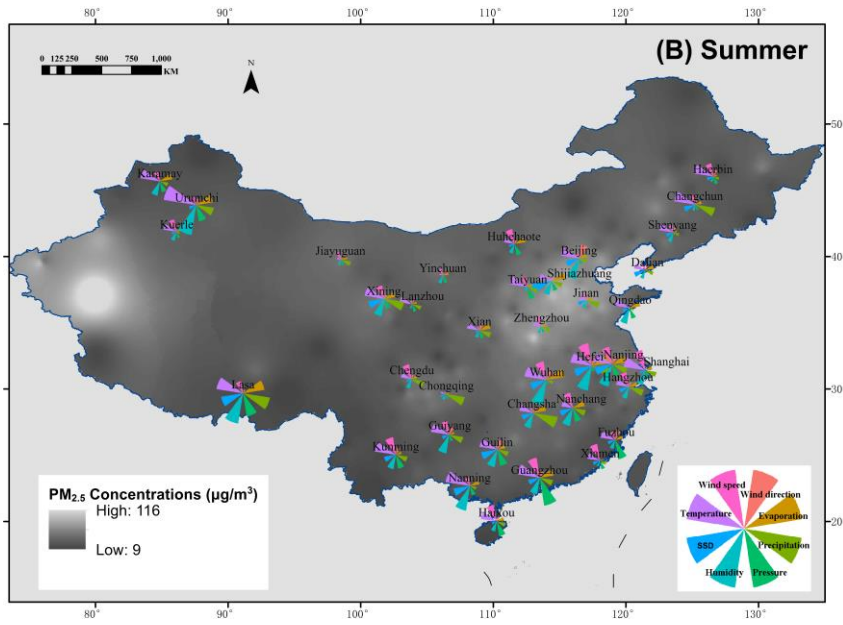

305 The ρ value is a direct indicator of quantitative causality. For this research, the
306 maximum ρ value of all sub-factors in the same category was used as the causality
307 of this specific meteorological factor on $PM_{2.5}$ concentrations. E.g. for a specific city, the
308 maximum ρ value of max temperature, mean temperature, minimum temperature, and
309 largest temperature difference for the day is used as the influence of temperature on local
310 $PM_{2.5}$ concentrations. For this research, we collected meteorological and $PM_{2.5}$ data for
311 three consecutive years. To avoid the analysis of inconsecutive time series, which may
312 influence the CCM result, we did not calculate the general influence of individual
313 meteorological factors on $PM_{2.5}$ concentrations during 2014-2016 by analyzing three
314 isolated periods (e.g. April- June, 2014, April-June, 2015, and April- June, 2016) as a
315 complete data set. Instead, for each city, we quantified the influence of individual
316 meteorological factors on $PM_{2.5}$ concentrations for each season in 2014, 2015 and 2016
317 respectively and calculated the mean ρ value during 2014-2016 for each city.

318 **4.1 Comprehensive meteorological influences on PM_{2.5} concentrations in some**
319 **regional representative cities**

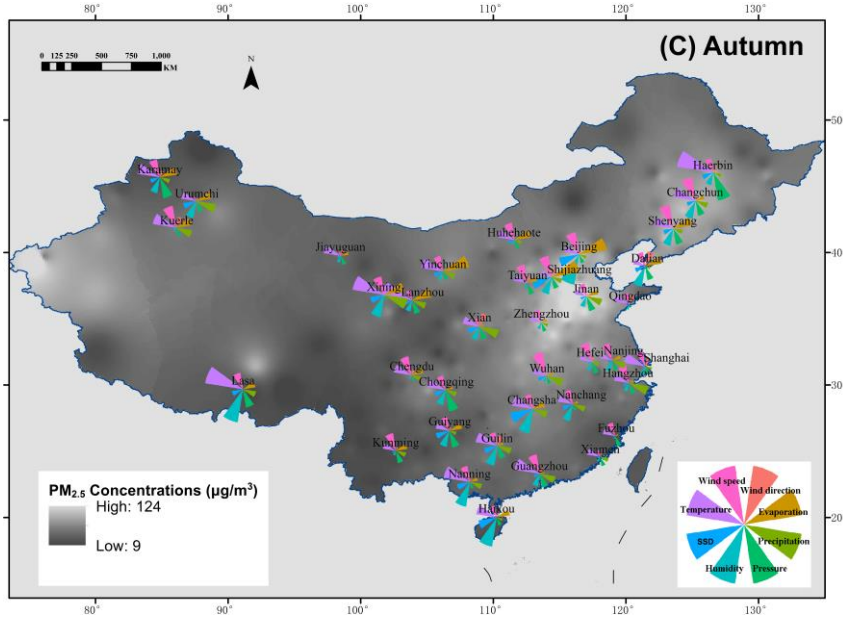

320 When the ρ value for each meteorological factor was calculated, a wind rose, which
321 presents the quantitative influences of all individual meteorological factors on PM_{2.5}
322 concentrations, can be produced for each city. It is not feasible to present all 188 wind
323 roses simultaneously, due to severe overlapping effects. Thus, considering the
324 social-economic factors, 37 regional representative cities (including all 31 provincial
325 capital cities in mainland China), which are the largest and most important cities for
326 specific regions, were selected to produce a wind rose map of meteorological influences
327 on PM_{2.5} concentrations across China (Fig 2).

328

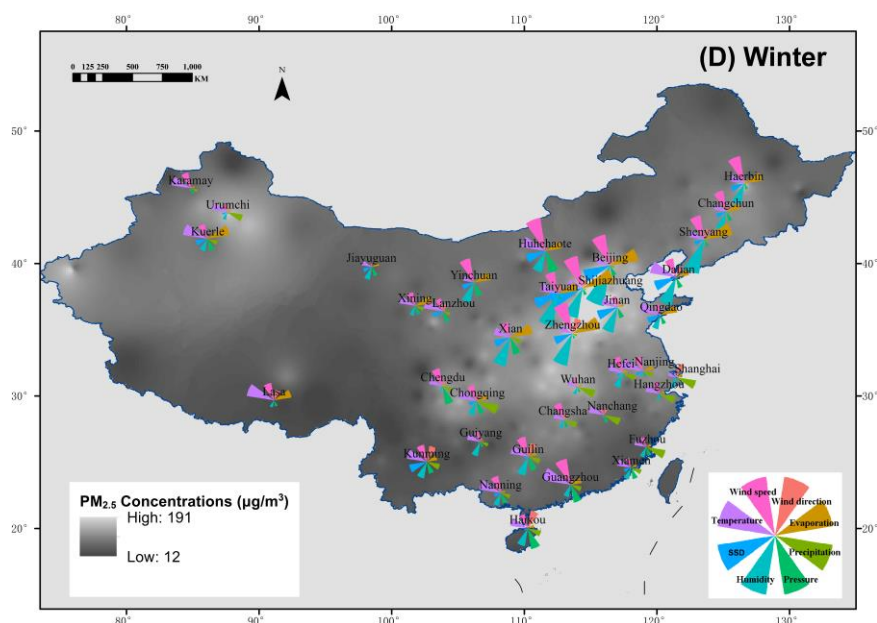

329

330

331

332 **Fig 2. Wind rose map of influences of eight individual meteorological factors on PM_{2.5}**
 333 **concentrations across mainland China (37 representative cities) during 2014-2016**

334

335 According to Fig 2, some spatial and temporal patterns of meteorological influences on
 336 PM_{2.5} concentrations at the national scale can be found as follows:

337 [a-1.](#)

338 Like seasonal variations of PM_{2.5} concentrations, the influences of individual
 339 meteorological factors on local PM_{2.5} concentrations vary significantly. For a specific city,
 340 the dominant meteorological driver for PM_{2.5} concentrations in one season may become
 341 insignificant in another season. E.g. in winter, one major meteorological influencing
 342 factor for Beijing is wind (The mean ρ value during 2014-2016 was 0.57), which
 343 exerts little influence on PM_{2.5} concentrations in summer (The mean ρ value during
 344 2014-2016 was 0.10). Furthermore, it is noted that seasonal variations of meteorological
 345 influences on PM_{2.5} concentrations apply to all these representative cities, as the shape
 346 and size of wind rose for each city change significantly across different seasons. Take
 347 several mega cities in different regions for instance. During 2014-2016, the three major
 348 meteorological influencing factors for PM_{2.5} concentrations in Beijing ([North China](#)
[plain](#)), [Shanghai](#) (Yangtze River Basin), [Wuhan](#) (Central China Region) and [Guangzhou](#)

349 ~~(South China Region) were listed as Table 1. a mega city in the North China plain,~~
350 ~~were as follows: humidity (0.48), wind (0.37) and evaporation (0.31) for spring,~~
351 ~~humidity (0.39), temperature (0.34) and SSD (0.25) for summer, humidity (0.56),~~
352 ~~evaporation (0.51) and wind (0.41) for autumn, and humidity (0.76), wind (0.57) and~~
353 ~~evaporation (0.52) for winter. The three major meteorological influencing factors for~~
354 ~~PM_{2.5} concentrations in Shanghai, a mega city in the Yangtze River Basin, were as~~
355 ~~follows: temperature (0.264), air pressure (0.260) and wind (0.25) for spring,~~
356 ~~temperature (0.40), wind (0.38) and humidity (0.27) for summer, temperature (0.39),~~
357 ~~wind (0.28) and humidity (0.17) for autumn, and precipitation (0.36), wind direction~~
358 ~~(0.25) and humidity (0.19) for winter. The three major meteorological influencing factors~~
359 ~~for PM_{2.5} concentrations in Wuhan, a major city in Central China region, were as follows:~~
360 ~~precipitation (0.18), wind (0.16) and temperature (0.09) for spring, humidity (0.47),~~
361 ~~temperature (0.41) and wind (0.34) for summer, wind (0.44), precipitation (0.31) and~~
362 ~~temperature (0.26) for autumn, and precipitation (0.33), temperature (0.19) and wind~~
363 ~~(0.15) for winter. The three major meteorological influencing factors for PM_{2.5}~~
364 ~~concentrations in Guangzhou, a major city in Southern China region, were as follows:~~
365 ~~wind (0.31), precipitation (0.24) and air pressure (0.23) for spring, air pressure (0.51),~~
366 ~~temperature (0.41) and wind (0.37) for summer, temperature (0.47), wind (0.36) and~~
367 ~~precipitation (0.29) for autumn, and temperature (0.52), wind (0.48) and air pressure~~
368 ~~(0.33). Notable According to Table 1, notable seasonal variations of meteorological~~
369 ~~influences on PM_{2.5} concentrations were found in these mega cities across China.~~

370 Table 1 Major meteorological influencing factors for PM_{2.5} concentrations in four mega
371 cities within different regions

372 b. In spite of notable differences in the shape and size of wind roses, meteorological
373 influences on PM_{2.5} concentrations cities are of some regional patterns. PM_{2.5}
374 concentrations in cities within the North China region are influenced by similar dominant
375 meteorological factors, especially in winter, when PM_{2.5} concentrations in these cities
376 are was high. Take four major cities, Beijing, Tianjin, Taiyuan and Shijiazhuang, in the
377 North China Plain for example. For winter, SSD, evaporation, humidity and wind were
378 the major meteorological factors for PM_{2.5} concentrations in the four cities and the ρ
379 value of these four factors was 0.50, 0.52, 0.76 and 0.57 for Beijing, 0.41, 0.44, 0.56 and
380 0.50 for Tianjin, 0.44, 0.36, 0.61 and 0.41 for Taiyuan, and 0.62, 0.58, 0.56 and 0.60 for
381 Shijiazhuang respectively, presenting a similar regional pattern. Meanwhile,
382 meteorological influences on PM_{2.5} concentrations in cities within the Yangtze River
383 Basin, especially the dominant factors, were also of some regional similarities. Take four
384 major cities in the Yangtze River Basin, Shanghai, Nanjing, Hangzhou and Nanchang for
385 example. For summer, precipitation, humidity, temperature and wind were the major

386 meteorological factors for PM_{2.5} concentrations in these four cities and the ρ value of
387 these factors was 0.21, 0.27, 0.40 and 0.38 for Shanghai, 0.29, 0.41, 0.34 and 0.33 for
388 Nanjing, 0.28, 0.27, 0.23 and 0.27 for Hangzhou, and 0.24, 0.33, 0.21 and 0.29 for
389 Nanchang. Despite ~~of~~ some differences in the ρ values, similar dominant
390 meteorological factors and the similar magnitude of meteorological influences
391 demonstrated regional similarities of meteorological influences on PM_{2.5} concentrations
392 in the Yangtze River Basin. –

393 As we can see, meteorological influences on PM_{2.5} concentrations in China are mainly
394 controlled by geographical conditions (e.g. terrain and landscape patterns).

395 [e3](#). For the heavily polluted North China region, the higher the local PM_{2.5} concentrations,
396 the larger influence meteorological factors exerts on PM_{2.5} concentrations. PM_{2.5}
397 concentrations are usually the highest in winter, causing serious air pollution episodes
398 across China, the North China region in particular. Meanwhile, PM_{2.5} concentrations in
399 spring and summer are comparatively low. Accordingly, there are more influencing
400 meteorological factors on PM_{2.5} concentrations for cities within this region and the ρ
401 value of these meteorological factors is notably larger in winter. Take [the summer and](#)
402 [winter major influencing meteorological factors for PM_{2.5} concentrations in](#) four major
403 cities [in the North China region](#) for instance ([as shown in Table 2](#)). ~~For Beijing, the~~
404 ~~major influencing meteorological factors in summer were temperature (0.34), humidity~~
405 ~~(0.39) and SSD (0.25) whilst the major influencing meteorological factors in winter~~
406 ~~were humidity (0.76), wind (0.57), evaporation (0.52) and SSD (0.5).~~ For Tianjin, the
407 ~~major influencing meteorological factors in summer were precipitation (0.34),~~
408 ~~temperature (0.22) and air pressure (0.25) whilst the major influencing meteorological~~
409 ~~factors in winter were humidity (0.76), wind (0.57), evaporation (0.52) and SSD (0.50).~~
410 ~~For Shijiazhuang, the major influencing meteorological factors in summer were SSD~~
411 ~~(0.4), humidity (0.26) and evaporation (0.26) whilst the major influencing~~
412 ~~meteorological factors in winter were SSD (0.62), wind (0.60), evaporation (0.58) and~~
413 ~~humidity (0.56).~~ For Taiyuan, the major influencing meteorological factors in summer
414 were temperature (0.32), air pressure (0.23) and precipitation (0.20) whilst the major
415 influencing meteorological factors in winter were humidity (0.61), SSD (0.44) and
416 ~~wind (0.41).~~ As explained, bidirectional interactions between meteorological factors and
417 PM_{2.5} concentrations may lead to complicated mechanisms that further enhance local

418 PM_{2.5} concentrations significantly. Therefore, strong meteorological influences on PM_{2.5}
 419 concentrations in winter are a major cause for the form and persistence of high PM_{2.5}
 420 concentrations within the North China region.

421 [Table 2 Summer and winter major influencing meteorological factors for PM_{2.5}](#)
 422 [concentrations in four major cities in the North China region](#)

423 —

424 4.2 Spatial and temporal variations of the dominant meteorological influence on 425 local PM_{2.5} concentrations across China

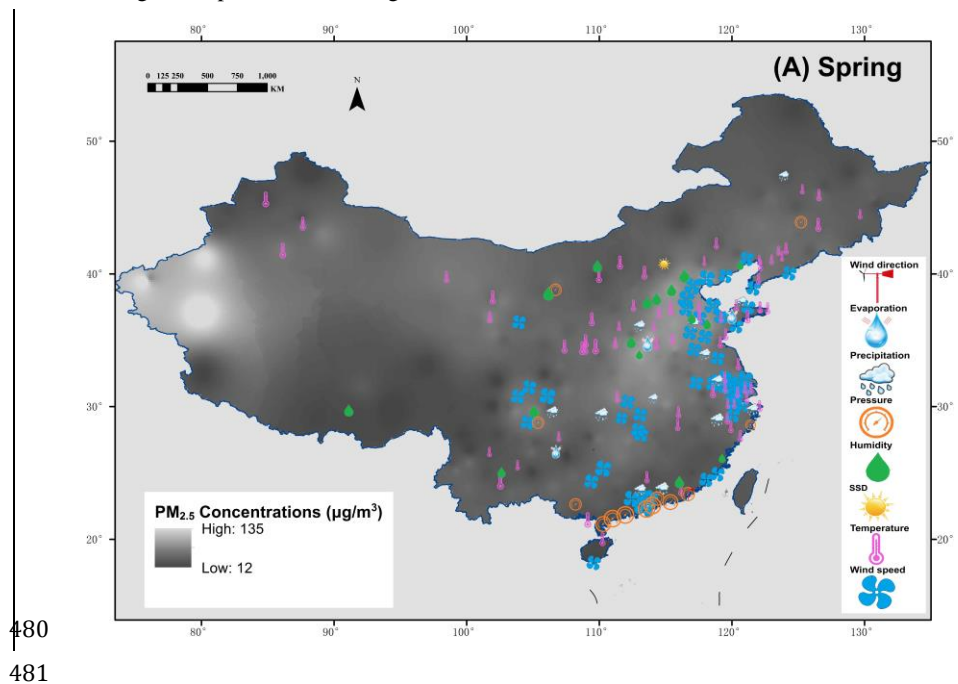

426 Through statistical analysis, we selected the factor with the largest ρ value as the
 427 dominant meteorological factor for local PM_{2.5} concentrations. The spatial and temporal
 428 variations of the dominant meteorological influence on local PM_{2.5} concentrations across
 429 China are demonstrated as Fig 3. According to Fig 3, some spatio-temporal
 430 characteristics of meteorological influences on PM_{2.5} concentrations can be further
 431 concluded:

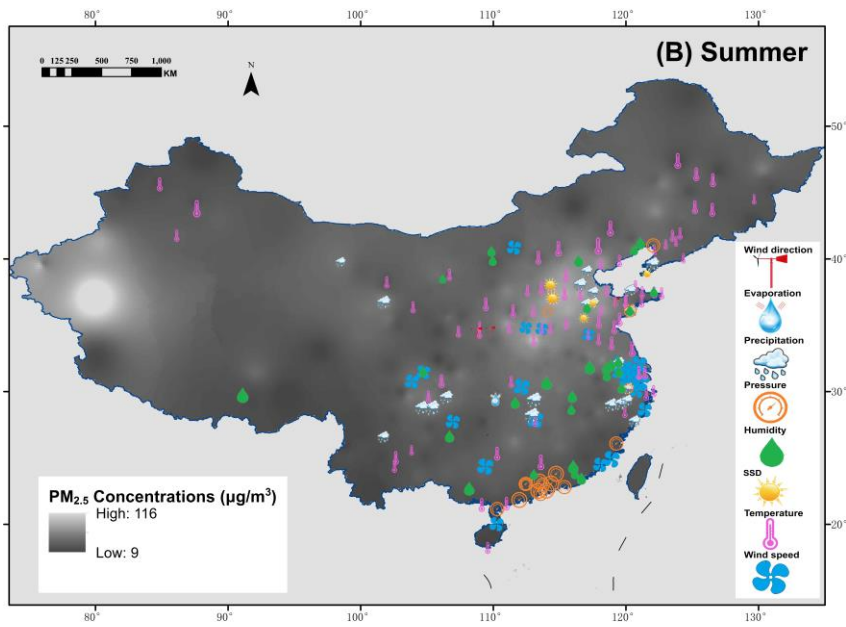

432 [a1](#). The dominant meteorological factor for PM_{2.5} concentrations is closely related to
433 geographical conditions. For instance, the factor of precipitation may exert a key
434 influence on local PM_{2.5} concentrations in some coastal cities and cities within the
435 Yangtze River Basin whilst this meteorological factor exerts limited influence on PM_{2.5}
436 concentrations within some inland regions. Here we analyzed the ρ value of
437 precipitation in cities within the Yangtze River Basin and cities within the
438 Beijing-Tianjin-Hebei region respectively. For winter, precipitation was the dominant
439 factor for PM_{2.5} concentrations in Shanghai, Hangzhou and Nanchang within the Yangtze
440 River Basin and the ρ value of precipitation was 0.36, 0.29 and 0.31 respectively.
441 Meanwhile, the ρ value of precipitation in Beijing, Tianjin and Shijiazhuang within the
442 Beijing-Tianjin-Hebei region was 0.08, 0.01 and 0.06 respectively.

443 [b2](#). Some meteorological factors can be the dominant factor for cities within different
444 regions ~~but~~whilst some (e.g. evaporation and SSD) are mainly the dominant
445 meteorological factor for PM_{2.5} concentrations in cities within some specific regions. In
446 other words, some factors can be regarded as regional and national meteorological
447 [influencing](#) factors for PM_{2.5} concentrations, yet some meteorological factors are
448 context-related influencing factors for local PM_{2.5} concentrations. Specifically, such
449 factors as temperature, wind and humidity serve as the dominant meteorological factors
450 in many regions, including Northeast, Northwest, coastal areas and inland areas;
451 Meanwhile, such factors as SSD and wind direction serve as the dominant
452 meteorological factors mainly in some inland regions. The prevalence of different
453 meteorological factors across China can also be reflected according to the number of
454 cities where this specific factor is the dominant factor for local PM_{2.5} concentrations. For
455 winter, the number of cities with temperature, wind or humidity as the dominant factor
456 was 56, 48 and 44 respectively. Meanwhile, the number of cities with SSD or wind
457 direction as the dominant factor was 3 and 1 respectively.

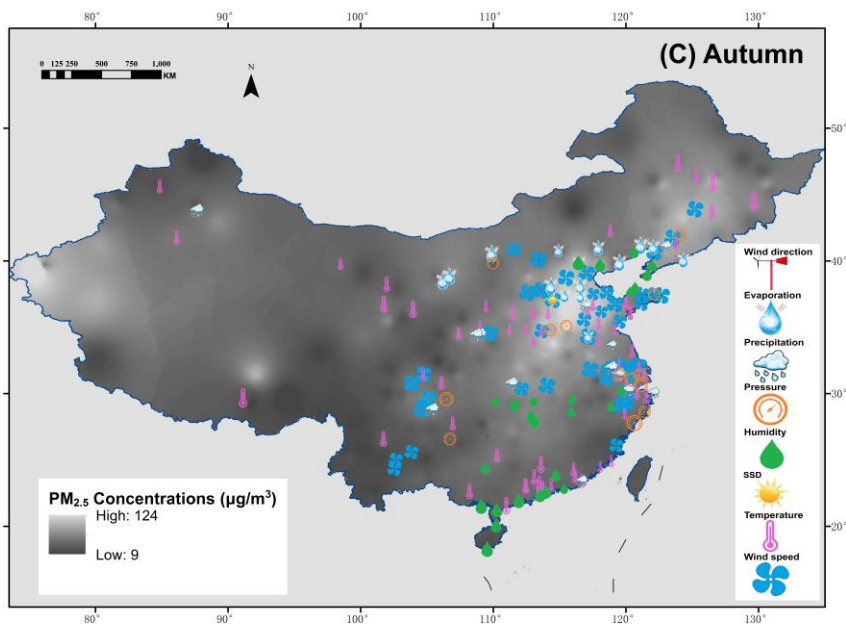

458 [e3](#). Similar to patterns revealed in Fig 2, the ρ value for the dominant meteorological
459 factors is much larger in winter than that in summer. Furthermore, it is noted that the
460 dominant meteorological factors demonstrate more regional similarity in winter.
461 Specially, the dominant meteorological factors for PM_{2.5} concentrations in the heavily
462 polluted North China region are more concentrated and homogeneously distributed in
463 winter (mainly the wind and humidity factor) whilst a diversity of dominant
464 meteorological factors (includes humidity, temperature, SSD and air pressure) for PM_{2.5}

465 concentrations is irregularly distributed within this region in summer. Take some major
 466 cities in North China region for instance. For winter, the dominant meteorological factors
 467 for Beijing, Tianjin, Taiyuan, Zhangjiakou, Handan and Jining was humidity (0.76),
 468 humidity (0.56), humidity (0.61), wind (0.62), humidity (0.43) and humidity (0.52)
 469 respectively. Meanwhile, for summer, the dominant meteorological factors for Beijing,
 470 Tianjin, Taiyuan, Zhangjiakou, Baoding, Handan and Jining was humidity (0.39),
 471 precipitation (0.28), temperature (0.23), temperature (0.47), air pressure (0.21) and SSD
 472 (0.18). According to this pattern, when a regional PM_{2.5}-induced air pollution episode
 473 occurs in winter, the regional air quality is more likely to be simultaneously improved by
 474 the same meteorological factor. This is consistent with the common scene in winter that
 475 regional air pollution episodes in the Beijing-Tianjin-Hebei region can be considerably
 476 mitigated by strong northwesterly synoptic winds, which are produced by presence of
 477 high air pressure in northwest Beijing (NW-High) (Tie et al., 2015; Miao et al., 2015).
 478 On the other hand, regional air pollution in summer can hardly be solved simultaneously
 479 through one specific meteorological factor.

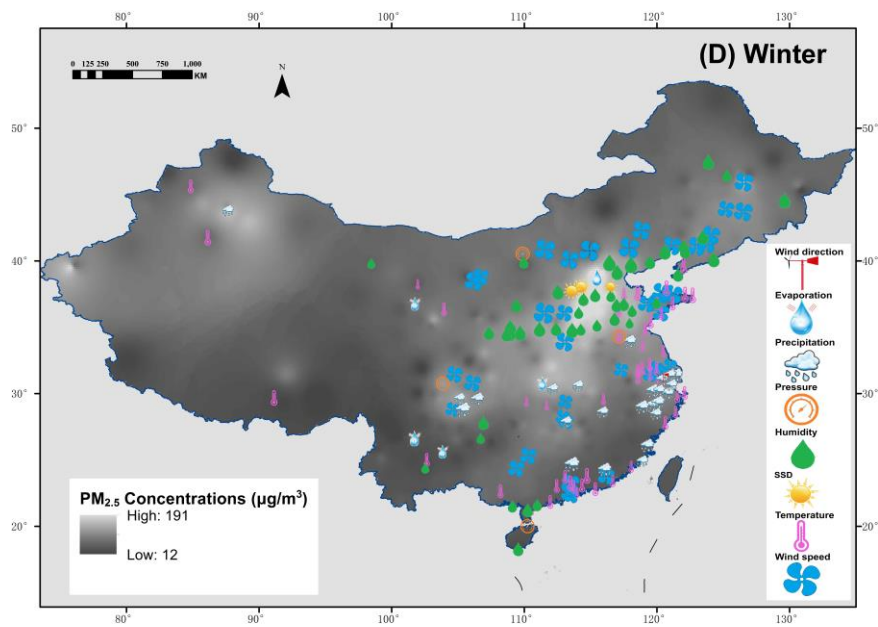

482

483

484

485 **Fig 3. The dominant meteorological factor for local PM_{2.5} concentrations in 188**
 486 **monitoring cities across mainland China**

487 The size of symbols indicates the ρ value of the meteorological factor on local PM_{2.5} concentrations.

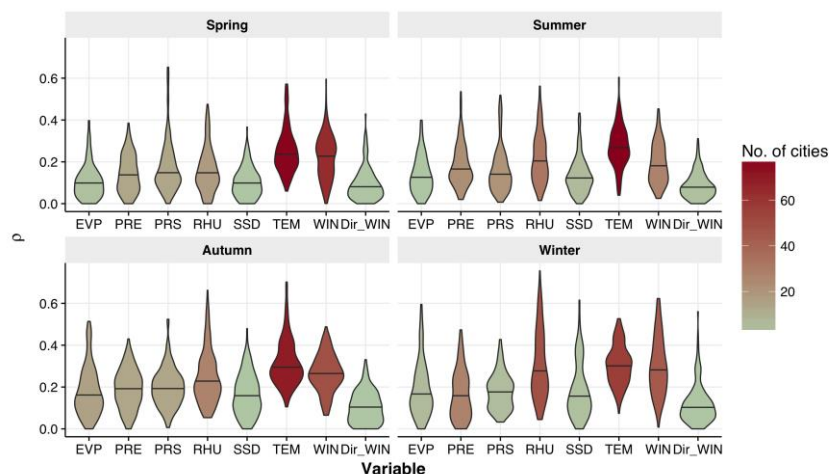

488 **4.3 Comparative statistics of the influence of individual meteorological factors on**
489 **local PM_{2.5} concentrations across China**

490 In addition to meteorological influences on PM_{2.5} concentrations for individual cities,
491 we examined and compared the comprehensive influence of individual meteorological
492 factors on PM_{2.5} concentrations at a national scale. The results are presented as Table
493 [4-3](#) and Fig 4.

494 **Table 4-3. The comparison of the influence of individual meteorological factors on**
495 **PM_{2.5} concentrations in 188 cities across China (2014-2016)**

Season	Factor	TEM	SSD	PRE	EVP	PRS	RHU	WIN	Dir_WIN
Spring	No. of cities ¹	76	1	13	3	13	17	64	1

	SD of ρ value	0.109	0.098	0.093	0.117	0.091	0.125	0.089	0.074
	Max ρ value	0.702	0.479	0.430	0.514	0.524	0.662	0.488	0.331
Winter	No. of cities	56	3	27	5	4	48	44	1
	Mean ρ value	0.306	0.183	0.166	0.190	0.180	0.304	0.299	0.119
	SD of ρ value	0.094	0.129	0.115	0.130	0.086	0.161	0.136	0.092
	Max ρ value	0.527	0.615	0.473	0.595	0.427	0.755	0.623	0.560

496 ¹No. of cities: the number of cities with this factor as the dominant meteorological factor (its ρ value
497 is the largest amongst eight factors) on local PM_{2.5} concentrations.

498
 499 **Fig 4. Violin plots of the influence of eight different meteorological factors on**
 500 **local PM_{2.5} concentrations in 188 cities across China**

501 No. of cities: the number of cities with this factor as the dominant meteorological factor (its
 502 ρ value is the largest amongst eight factors) on local PM_{2.5} concentrations. The shape of the
 503 violin bars indicated the frequency distribution of ρ value for 188 cities.

504 We compared the influence of individual meteorological factors on PM_{2.5}
 505 concentrations from different perspectives.

506 **a1.** From a national perspective, temperature, humidity, and wind exert stronger
 507 influences on local PM_{2.5} concentrations than other factors. The annual mean ρ value
 508 for temperature, wind and humidity was 0.287, 0.244 and 0.233, compared with wind
 509 direction (0.101), SSD (0.146), evaporation (0.155), precipitation (0.171) and air
 510 pressure (0.180). Amongst the eight factors, temperature was found to be the most
 511 influential meteorological factor for general PM_{2.5} concentrations in China. In
 512 addition to the largest mean ρ value, temperature was the dominant meteorological
 513 factors for most cities in all seasons. Furthermore, the Coefficient of Variation (SD
 514 /mean \times 100%) for temperature was much smaller than other factors, indicating the
 515 consistent influence of temperature on local PM_{2.5} concentrations across China.

516 **b2.** Although some meteorological factors exert a limited influence on PM_{2.5}
 517 concentrations at a national scale, these factors may be a key meteorological factor for
 518 local PM_{2.5} concentrations. As shown in Table 1, the max ρ value for each

519 meteorological factor was large than 0.35 for all seasons (except for the wind
520 direction factor in summer and autumn), indicating a very strong influence on local
521 PM_{2.5} concentrations in some specific regions. As a result, when analyzing
522 meteorological influences on local PM_{2.5} concentrations for a specific city,
523 meteorological factors that have little influence on PM_{2.5} concentrations at a large
524 scale should also be comprehensively considered.

525 e3. Some factors (e.g. precipitation in summer and winter) may be the dominant
526 meteorological factors for a large number of cities, though the mean ρ value
527 remained small. This may be attributed to the fact that these meteorological factors
528 mainly exert influence on local PM_{2.5} concentrations in those cities (seasons) where
529 (when) the general PM_{2.5} concentrations is not high. Taking the precipitation as an
530 example. Luo et al. (2017) pointed out that there may be thresholds for the negative
531 influences of precipitations on PM_{2.5} concentrations and Guo et al. (2016) found that
532 the same amount of precipitation led to a weaker washing-off effect in areas with
533 higher PM_{2.5} concentrations. Hence, precipitation mainly exerts a dominant influence
534 on local PM_{2.5} concentrations in winter for Yangtze River Basin or coastal cities,
535 where the amount of precipitation is large and the PM_{2.5} concentration is low, whilst
536 precipitation exerts a limited role in northern China, where the amount of
537 precipitation is small and the PM_{2.5} concentration is high. Therefore, as explained
538 above, comprehensive meteorological influences on PM_{2.5} concentrations are limited
539 considerably.

540 5 Discussion

541 ~~Despite the lack of a comprehensive comparison of meteorological influences on~~
542 ~~PM_{2.5} concentrations across different regions, c~~Correlations between individual
543 meteorological factors and PM_{2.5} concentrations have been analyzed in such mega
544 cities as Nanjing (Chen, T. et al, 2016; Shen and Li, 2016;), Beijing (Huang et al,
545 2015; Yin et al, 2016), Wuhan (Zhang et al, 2017), Hangzhou (Jian et al, 2012),
546 Chengdu (Zeng and Zhang, et al 2017) and Hong Kong (Fung et al, 2014). These
547 studies ~~mainly employed correlation analysis to quantify the influence of several~~
548 ~~meteorological factors on PM_{2.5} concentrations and~~ suggested that meteorological
549 influences on PM_{2.5} concentrations varied significantly across regions. The
550 dominant meteorological factors for P_{2.5} concentrations ~~(presented as the largest~~

带格式的: 下标

551 ~~correlation coefficients in previous studies and the largest P value in this research~~
552 demonstrated notable regional differences. For Nanjing (Chen, T. et al, 2016), a
553 mega city in the Yangtze River, and Hong Kong (Fung et al, 2014), a mega coastal
554 city, precipitation exerted the strongest influence whilst wind speed exerted a
555 weak influence on PM_{2.5} concentrations in winter. On the other hand, for winter,
556 wind speed was the dominant meteorological factor for PM_{2.5} concentrations in
557 Beijing (Huang et al, 2015.) , a mega city in North China, and precipitation played
558 a weak role in affecting local PM_{2.5} concentrations . ~~These studies generally~~
559 ~~analyzed and compared the influences of different meteorological factors on PM_{2.5}~~
560 ~~concentrations and extracted the dominant meteorological influencing factors for~~
561 ~~specific areas.~~ Compared with studies at a local or regional scale, this research
562 conducted at the national scale provided a better understanding of spatial and
563 temporal patterns of meteorological influences on PM_{2.5} concentrations across China,
564 for the following reasons. a. A national perspective. Previous studies conducted at a
565 local scale mainly focused on a specific city (e.g. Beijing), and can hardly reveal
566 spatio-temporal patterns of meteorological influences on PM_{2.5} concentrations at a
567 large scale (e.g. the North China plain). This research, on the other hand, quantified
568 the influence of meteorological factors on PM_{2.5} concentrations for 188 cities across
569 China, and thus revealed some regional patterns of meteorological influences on
570 PM_{2.5} concentrations in some typical regions (e.g. North China region or Yangtze
571 River Basin). b. A unified research period and set of meteorological factors. Previous
572 studies employed short-term observation data (e.g. one season or one year) ~~to~~
573 ~~examine the meteorological influences on local PM_{2.5} concentrations~~ in specific cities.
574 Due to the discrepancy in research periods and sets of meteorological factors, the
575 findings from different local-scale studies cannot be compared and comprehensively
576 understood. This research employed daily PM_{2.5} and meteorological data of three
577 consecutive years and a unified set of eight meteorological factors for all 188
578 monitoring cities and thus meteorological influences on PM_{2.5} concentrations across
579 China can be effectively compared without significant influences from inter-annual
580 variations. c. A robust causality analysis method. ~~Due to complicated interactions~~
581 ~~between different meteorological factors,~~ ~~e~~Correlations analysis, as introduced above,
582 may lead to large bias in quantifying the meteorological influences on PM_{2.5}
583 concentrations. Similarly, the correlation coefficient ~~between individual~~

584 ~~meteorological factors and PM_{2.5} concentrations~~ cannot be used as a reliable indicator
585 to compare quantitative influences of individual meteorological factors on PM_{2.5}
586 ~~concentrations~~ across different cities. This research employed a robust CCM method,
587 which removes the influence of other factors, and effectively quantified the coupling
588 between PM_{2.5} concentrations and a set of meteorological factors. The ρ value of
589 each meteorological factor on PM_{2.5} concentration can be compared between different
590 cities. Based on national statistics across China, this research concluded that the
591 influence of temperature, humidity and wind, especially temperature, on PM_{2.5}
592 concentrations was much larger than that of other meteorological factors, which could
593 not be revealed by previous local and regional scale studies.

594
595 The findings from this research were consistent with and a major extension of those
596 from previous studies by quantifying the influence of individual meteorological
597 factors in a large number of cities across China using a more robust causality analysis
598 method. Similar to previous studies, this study also revealed notable differences in
599 meteorological influences on PM_{2.5} concentrations at the national scale, ~~the major~~
600 ~~reason for~~ which was mainly attributed to different meteorological conditions and
601 complicated mechanisms of PM_{2.5}-meteorology interactions. Firstly, notable
602 differences existed in meteorological conditions across China. For instance, in winter,
603 the frequency and intensity of precipitation are much higher and stronger in coastal
604 areas than those in the North China region, where the frequency of strong winds is
605 high in winter. Therefore, precipitation exerts a large influence on PM_{2.5}
606 concentrations in coastal regions whilst wind is the key influencing factor for PM_{2.5}
607 concentrations in the North China region in winter. Secondly, in addition to the large
608 variations in the values of correlation coefficients, the interaction mechanisms
609 between individual meteorological factors and PM_{2.5} concentrations may also vary
610 significantly across regions. For such meteorological influences as wind speed, its
611 negative effect on PM_{2.5} concentrations was consistent in China (He et al., 2017). On
612 the other hand, He et al. (2017) suggested that temperature and humidity were either
613 positively or negatively correlated with PM_{2.5} concentrations in different regions of
614 China. In terms of humidity, when the humidity is low, PM_{2.5} concentration increases
615 with the increase of humidity due to hygroscopic increase and accumulation of PM_{2.5}
616 (Fu et al., 2016). When the humidity continues to grow, the particles grow too heavy

617 to stay in the air, leading to dry (particles drop to the ground) (Wang, J., & Ogawa, S.
618 (2015)) and wet deposition (precipitation) (Li et al., 2015b), and the reduction of
619 PM_{2.5} concentrations. Similarly, there may be thresholds for the negative influences of
620 precipitations on PM_{2.5} concentrations (Luo et al., 2017). Heavy precipitation can
621 have a strong washing-off effect on PM_{2.5} concentrations and notably reduce PM_{2.5}
622 concentrations. Meanwhile, slight precipitation may not effectively remove the
623 high-concentration PM_{2.5}. Instead, the slight precipitation may induce enhanced
624 relative humidity and thus lead to the increase of PM_{2.5} concentrations. Meanwhile,
625 the washing-off effect from the same amount of precipitation on PM_{2.5} concentrations
626 in Xi'an, a city with higher PM_{2.5} concentrations, was lower than that in Guangzhou
627 (Guo et al., 2016), indicating local PM_{2.5} concentrations also exerted a key role in the
628 negative effects of precipitation. Meanwhile, temperature can either be negatively
629 correlated with PM_{2.5} concentrations by accelerating the flow circulation and
630 promoting the dispersion of PM_{2.5} (Li et al., 2015b), or positively correlated with
631 PM_{2.5} concentrations through inversion events (Jian et al., 2012). Given the
632 complexity of interactions between meteorological factors and PM_{2.5}, characteristics
633 and variations of ~~influences of individual~~ meteorological ~~factors influences~~ on PM_{2.5}
634 concentrations should be further investigated for specific regions across China
635 respectively based on long-term observation data.

636 Due to highly complicated atmospheric environment and the difficulty in acquiring
637 true data of exhaust emission, commonly used models for air quality prediction(e.g.
638 CAMx, CMAQ and WRFCHM) may lead to large biases and uncertainty when
639 applied to China. On the other hand, ~~without prior knowledge of mechanisms of high~~
640 ~~PM_{2.5} concentrations and information of exhaust emission,~~ statistical models can
641 achieve satisfactory forecasting results based on massive historical data (Cheng et al.,
642 2015). Compared with the static models, dynamic statistical models additionally
643 consider the meteorological influences on PM_{2.5} concentrations and some
644 meteorological factors that are of stable, representative and strong correlations with
645 PM_{2.5} ~~concentrations~~ are selected for forecasting PM_{2.5} concentrations. Meanwhile,
646 many recent studies (Cheng et al., 2017; Guo et al., 2017; Lu et al., 2017; Ni et al.
647 2017; etc) have recognized the meteorological influences on the evolution of PM_{2.5}
648 concentrations and included some key meteorological factors ~~in their models~~ for
649 PM_{2.5} estimation. However, most PM_{2.5} estimation and forecasting models mainly

650 employed correlation analysis ~~to reveal the influence of individual meteorological~~
651 ~~factors on PM_{2.5} concentrations. Due to complicated interactions in atmospheric~~
652 ~~environment, and~~ the correlation coefficient between meteorological factors and
653 PM_{2.5} concentrations is usually much larger than the ρ value and overestimates the
654 influence of individual meteorological factors on PM_{2.5} concentrations. In this case,
655 this research provides useful reference for improving existing statistical models. By
656 incorporating the ρ value, instead of the correlation coefficient, of different factors
657 into corresponding GAM (Generalized Additive Models) and adjusting parameters
658 accordingly, we may significantly improve the reliability of future estimation and
659 forecasting of PM_{2.5} concentrations.

660 Quantified causality of individual meteorological factors on PM_{2.5} concentrations
661 provides useful decision support for evaluating relevant environmental projects,
662 ~~which aim to improve local and regional air quality through meteorological~~
663 ~~means~~. Specifically, a forthcoming Beijing wind-corridor project
664 (http://www.bj.xinhuanet.com/bjyw/yqphb/2016-05/16/c_1118870801.htm) has
665 become a hot social and scientific issue. Herein, our research suggests that wind is a
666 dominant meteorological factor for winter PM_{2.5} concentrations in Beijing and can
667 significantly influence PM_{2.5} concentrations through direct and indirect
668 mechanisms(Chen,Z. et al., 2017). In consequence, the wind-corridor project may
669 directly allow in more strong wind, which thus leads to a larger value of SSD and
670 ~~evaporationEVP~~ and a smaller value of ~~RHUhumidity~~. The change of SSD,
671 ~~humidityRHU~~ and ~~evaporationEVP~~ values can further induce the reduction of PM_{2.5}
672 concentrations. From this perspective, the Beijing wind-corridor project has good
673 potential to improve local and regional air quality. In addition ~~to the wind-corridor~~
674 ~~project~~, some scholars and decision makers have proposed other meteorological
675 means for reducing PM_{2.5} concentrations. For instance, Yu (2014) suggested that water
676 spraying from high buildings and water towers in urban areas was an efficient way to
677 reduce PM_{2.5} concentrations rapidly by simulating ~~the process of~~ precipitation.
678 However, some limitations, such as the humidity control and potential icing risk,
679 remained. In the near future, with growing attention on the improvement of air quality,
680 more environmental projects should be properly designed and implemented.
681 According to this research, ~~meteorological influences on PM_{2.5} concentrations vary~~

682 notably across China. Given the diversity of dominant meteorological factors on
683 local PM_{2.5} concentrations in different regions and seasons, it is more efficient to
684 design meteorological means accordingly. For the heavily polluted North China
685 region, especially the Beijing-Tianjin-Hebei region, the northwesterly synoptic wind
686 (Tie et al., 2015; Miao et al., 2015) is much stronger in winter than winds in summer
687 and exerts a dominant influence on PM_{2.5} concentrations (Chen et al., 2017).
688 Furthermore, in North China, the PM_{2.5} concentration is much more sensitive to the
689 change of wind speed than that of other meteorological factors (Gao et al., 2016).
690 Meanwhile, wind-speed induced climate change led to the change of PM_{2.5}
691 concentrations by as much as 12.0 µgm⁻³, compared with the change of PM_{2.5}
692 concentrations by up to 4.0 µgm⁻³ in south-eastern, northwestern and south-western
693 China (Tai et al., 2010). ~~Considering the strong winds in winter, the dominant~~
694 ~~influence of wind speed on PM_{2.5} concentrations and the sensitivity of PM_{2.5}~~
695 ~~feedbacks to the change of wind speed, Therefore,~~ meteorological means for
696 encouraging strong winds are more likely to reduce PM_{2.5} concentrations considerably
697 in North China. Similarly, Luo et al. (2017) suggested that only precipitation with a
698 certain magnitude can lead to the washing-off effect of PM_{2.5} concentrations whilst
699 Guo et al. (2016) revealed that the variation of PM_{2.5} concentrations was more
700 sensitive to the same amount of precipitation in areas with lower PM_{2.5} concentrations.
701 Therefore, meteorological means for inducing precipitation are more likely to
702 improve air quality in coastal cities and cities within the Yangtze River basin, where
703 there is a large amount of precipitation and relatively low PM_{2.5} concentrations.

704 **6 Conclusions**

705 Previous studies examined the correlation between individual meteorological
706 influences and PM_{2.5} concentrations in some specific cities and the comparison
707 between these studies indicated that meteorological influences on PM_{2.5}
708 concentrations varied significantly across cities and seasons. However, these scattered
709 studies conducted at the local scale cannot reveal regional patterns of meteorological
710 influences on PM_{2.5} concentrations. Furthermore, previous studies generally selected
711 different research periods and meteorological factors, making the comparison of
712 findings from different studies less robust. Thirdly, these studies employed the
713 correlation analysis, which may be biased significantly due to the complicated

714 interactions between individual meteorological factors. This research is a major
715 extension of previous studies. Based on a robust causality analysis method CCM,
716 we quantified and compared the influence of eight meteorological factors on local
717 PM_{2.5} concentrations for 188 monitoring cities across China using PM_{2.5} and
718 meteorological observation data from [March, 2014](#) to [February, 2017](#). Similar to
719 previous studies conducted at the local scale, this research further indicated that
720 meteorological influences on PM_{2.5} concentrations were of notable seasonal and
721 spatial variations at the national scale. Furthermore, this research revealed some
722 regional patterns and comprehensive statistics of the influence of individual
723 meteorological factors on PM_{2.5} concentrations, which cannot be understood through
724 small-scale case studies. For the heavily polluted North China region, the higher
725 PM_{2.5} concentrations, the stronger influence meteorological factors exert on local
726 PM_{2.5} concentrations. The dominant meteorological factor for PM_{2.5} concentrations is
727 closely related to geographical conditions. For heavily polluted winter, precipitation
728 exerts a key influence on local PM_{2.5} concentrations in most coastal areas and the
729 Yangtze River basin, whilst the dominant meteorological driver for PM_{2.5}
730 concentrations is wind in the North China regions. At the national scale, the influence
731 of temperature, humidity and wind on local PM_{2.5} concentrations is much larger than
732 that of other factors, and temperature exerts the strongest and most stable influences
733 on national PM_{2.5} concentrations in all seasons. The influence of individual
734 meteorological factors on PM_{2.5} concentrations extracted in this research provides
735 more reliable reference for better modelling and forecasting local and regional PM_{2.5}
736 concentrations. Given the significant variations of meteorological influences on PM_{2.5}
737 concentrations across China, environmental projects aiming for improving local air
738 quality should be designed and implemented accordingly.
