

## Reply to Anonymous Referee #1

We thank the reviewer for the careful reading of the manuscript and helpful comments. We have revised the manuscript following the suggestion, as described below.

In this study, authors used WRF-Chem model to simulate a heavy haze pollution episode from 05 December 2015 to 04 January 2016 in the North China Plain (NCP) to study contributions of the aerosol shortwave radiative feedback (ARF) to near-surface PM<sub>2.5</sub> mass concentrations. The topic is within ACP scope. Although such studies have been done for Europe (Forkel et al., 2012) or Eastern China (Zhang et al., 2015), this study focused a high PM<sub>2.5</sub> event at the NCP. I would like to see my below comments well addressed before the official publication of the manuscript in ACP. Forkel, R., Werhahn, J., Hansen, A. B., McKeen, S., Peckham, S., Grell, G., and Suppan, P.: Effect of aerosol-radiation feedback on regional air quality-A case study with WRF/Chem, *Atmospheric environment*, 53, 202-211, 2012. Zhang, B., Wang, Y., and Hao, J.: Simulating aerosol-radiation-cloud feedbacks on meteorology and air quality over eastern China under severe haze conditions in winter, *Atmospheric Chemistry and Physics*, 15, 2387-2404, 2015.

**Response:** We thank the reviewer for the helpful comment and have clarified in Introduction: *“Online-coupled meteorology and chemistry models have also been used to verify the impact of ARF on the PBLH and near-surface [PM<sub>2.5</sub>] during haze episodes in Europe, Eastern China and Northern China (Forkel et al., 2012; Z. Wang et al., 2014; Wang et al., 2015; Zhang et al., 2015; Gao et al., 2015). However, the ARF impact on near-surface [PM<sub>2.5</sub>] varies, depending on the evaluation time and location (Table 1).”* We have also included the results of Zhang et al. (2015) into Table 1.

**1 Comment:** The paper has certain unprofessional usages that hinder the reading, examples from Abstract are:

- a. WRF-Chem is the official name, avoid using WRF-CHEM
- b. Line 18: Atmospheric aerosols are different from fine particulate matters
- c. Line 30, there are two “during the episode” separated by a “.”
- d. Line 34, how do you “cooling the temperature”
- e. Lines 32-36, this sentence has mixed verb tenses, not clear what leads to leads.
- f. In Line 32, “Sensitivity studies have revealed” while in Line 37 “ensemble analysis

indicates”

- g. How “near-surface” is defined?
- h. I don’t think “the” is needed in front of ARF, but it is needed in front of NCP
- i. Do not use [PM<sub>2.5</sub>]
- j. Line 98, correct the WRF name-the Weather Research and Forecasting (WRF)

**Response:**

- a. We have revised the “WRF-CHEM” as “WRF-Chem” in the manuscript.
- b. We have removed “*fine particulate matters (PM<sub>2.5</sub>)*” in Abstract.
- c. We have removed the first “during the episode”.
- d. We have changed “*cooling the temperature of the low-level atmosphere*” as “*to cool the low-level atmosphere*”.
- e. We have rephrased the sentence as “*Sensitivity studies have revealed that high loadings of PM<sub>2.5</sub> attenuate the incoming solar radiation reaching the surface to cool the low-level atmosphere, suppressing development of PBL, decreasing the surface wind speed, further hindering the PM<sub>2.5</sub> dispersion and consequently exacerbating the haze pollution in the NCP.*”
- f. We have changed “*The ensemble analysis indicates*” to “*Furthermore*”.
- g. We have clarified in Abstract: “*near-surface (around 15 m above the ground surface)*”.
- h. We have revised “*the ARF*” as “*ARF*” and “*NCP*” as “*the NCP*” in the manuscript.
- i. We have defined “PM<sub>2.5</sub> concentrations” as “[PM<sub>2.5</sub>]” for convenience in Section 1.
- j. We have corrected the WRF name as “*the Weather Research and Forecasting (WRF)*” in Section 1.

**2 Comment:** What is the definition of haze pollution? I understand the authors want to say high PM<sub>2.5</sub> concentration. But is haze pollution some well-defined concept, any criteria to that?

**Response:** We have clarified in Section 2.1: “*During the study episode, the average hourly [PM<sub>2.5</sub>] in the NCP are approximately 127.9 μg m<sup>-3</sup>, within the fourth grade of National Ambient Air Quality Standards with [PM<sub>2.5</sub>] between 115 and 150 μg m<sup>-3</sup> (moderately polluted, Feng et al., 2016). The persistent and widespread haze pollution episode with high [PM<sub>2.5</sub>] in the NCP provides a suitable case for observation analyses and model simulations to investigate ARF effect on haze pollution.*”.

**3 Comment:** What version of WRF-Chem is used? We do appreciate the authors' efforts on improving the model, but the WRF-Chem has been developed much further since 2005 version. How did the authors incorporate the new features of the new versions? The authors also need provide reasons why the old things are used when new versions have been out for many years for the parts they modified, i.e., CMAQ aerosol module (AERO5 or AERO6?), ISORROPIA 1.7 as ISORROPIA II has been out since 2007.

**Response:** We have clarified in Section 3.3:

*“The WRF-Chem model (Grell et al., 2005) with modifications by Li et al. (2010, 2011a, b, 2012) is applied to evaluate effects of ARF on the wintertime haze formation in the NCP. The model includes a new flexible gas phase chemical module, which can be used with different chemical mechanisms, such as CBIV, RADM2, and SAPRC. In the study, the SAPRC99 chemical mechanism is used based on the available emission inventory. For the aerosol simulations, the CMAQ/models3 aerosol module (AERO5) developed by US EPA has been incorporated into the model (Binkowski and Roselle, 2003). The wet deposition is based on the method in the CMAQ module and the dry deposition of chemical species follows Wesely (1989). The photolysis rates are calculated using the FTUV (fast radiation transfer model) with the aerosol and cloud effects on photolysis (Li et al., 2005, 2011a).*

*It is worth noting that the most recent extension of ISORROPIA, known as ISORROPIA II, has incorporated a larger number aerosol species (Ca, Mn, K salts) and is designed to be a superset of ISORROPIA (Fountoukis et al., 2009). However, the ISORROPIA Version II uses the exact same routines as ISORROPIA to compute the equilibrium composition, which produces identical results as ISORROPIA when crustal species are not considered. Therefore, the inorganic aerosols in this study are predicted using ISORROPIA Version 1.7, calculating the composition and phase state of an ammonium-sulfate-nitrate-water inorganic aerosol in thermodynamic equilibrium with gas phase precursors (Nenes, 1998). In addition, a parameterization of sulfate heterogeneous formation involving aerosol liquid water (ALW) has been developed and implemented into the model, which has successfully reproduced the observed rapid sulfate formation during haze days (Li et al., 2017a). The sulfate heterogeneous formation from SO<sub>2</sub> is parameterized as a first order irreversible uptake by ALW surfaces, with a reactive uptake coefficient of  $0.5 \times 10^{-4}$  assuming that there is enough alkalinity to maintain the high iron-catalyzed reaction rate.*

*The OA module is based on the VBS approach with aging and detailed information can be found in Li et al. (2011b). The POA components from traffic-related combustion and*

biomass burning are represented by nine surrogate species with saturation concentrations ( $C^*$ ) ranging from  $10^{-2}$  to  $10^6 \mu\text{g m}^{-3}$  at room temperature (Shrivastava et al., 2008), and assumed to be semi-volatile and photochemically reactive (Robinson et al., 2007). The SOA formation from each anthropogenic or biogenic precursor is calculated using four semi-volatile VOCs with effective saturation concentrations of 1, 10, 100, and  $1000 \mu\text{g m}^{-3}$  at 298 K. The SOA formation via the heterogeneous reaction of glyoxal and methylglyoxal is parameterized as a first-order irreversible uptake by aerosol particles with an uptake coefficient of  $3.7 \times 10^{-3}$  (Liggio et al., 2005; Zhao et al., 2006; Volkamer et al., 2007).”.

**4 Comment:** Lines 176-182, put these equations to appendix.

**Response:** We have moved these equations to the Supplement Section S1.

**5 Comment:** What is the difference between summary and conclusions? Reduce the length of this section, do not repeat the main results.

**Response:** We have revised “*Summary and conclusions*” as “*Conclusions*” in Section 4, and also reduced the length of the section.

**6 Comment:** The results are normal and well described, although the main findings (Figures 11-15) are much less compared to the model validation figures (1-10). It is suggested to consider adjusting that if ACP is sensitive to the length of articles.

**Response:** We have moved the model validation of air pollutants and aerosol species to the supplement to shorten the part of model evaluations, and clarified in Section 3.1: “*Generally, the model simulates well the horizontal distributions and temporal variations of  $\text{PM}_{2.5}$ ,  $\text{O}_3$ ,  $\text{NO}_2$ , and  $\text{SO}_2$  mass concentrations against measurements in the NCP. Additionally, the model also reasonably well reproduces the temporal profiles of the aerosol species compared to observations in Beijing. The detailed model validation of air pollutants in the NCP and the aerosol species in Beijing can be found in SI.*”
