1 **Abstract.** Light-absorbing particles (LAPs) deposited on snow can decrease snow  
2 albedo and affect climate through the snow-albedo radiative forcing. In this study, we  
3 use MODIS observations combined with a snow albedo model (SNICAR) and a  
4 radiative transfer model (SBDART) to retrieve the radiative forcing by LAPs in snow  
5 ( $RF_{MODIS}^{LAPs}$ ) across Northeastern China (NEC) in January-February from 2003 to 2017.  
6  $RF_{MODIS}^{LAPs}$  presents distinct spatial variability, with the minimum ( $22.3 \text{ W m}^{-2}$ ) in western  
7 NEC and the maximum ( $64.6 \text{ W m}^{-2}$ ) near industrial areas in central NEC. The regional  
8 mean  $RF_{MODIS}^{LAPs}$  is  $\sim 45.1 \pm 6.8 \text{ W m}^{-2}$  in NEC. The positive (negative) uncertainties of  
9 retrieved  $RF_{MODIS}^{LAPs}$  due to atmospheric correction range from 14% to 57% (-14% to -  
10 47%) and the uncertainty value basically decreased with the increased  $RF_{MODIS}^{LAPs}$ . We  
11 attribute the variations of radiative forcing based on remote sensing and find that the  
12 spatial variance of  $RF_{MODIS}^{LAPs}$  in NEC is 74.6% due to LAPs, while 21.2% and 4.2% due  
13 to snow grain size, and solar zenith angle. Furthermore, based on multiple linear  
14 regression, the BC dry and wet deposition and snowfall could totally explain 81% of  
15 the spatial variance of LAP contents, which confirms the reasonability of the spatial  
16 patterns of retrieved  $RF_{MODIS}^{LAPs}$  in NEC. We validate  $RF_{MODIS}^{LAPs}$  using in situ radiative  
17 forcing estimates. We find that the biases in  $RF_{MODIS}^{LAPs}$  are negatively correlated with  
18 LAP concentrations and range from  $\sim 5\%$  to  $\sim 350\%$  in NEC.

1 1. Introduction

2 Pure snow is the most strongly reflective natural substance at the surface of the Earth,  
3 and seasonal snow covers more than 30% of the Earth's land area (Painter et al., 1998).  
4 Therefore, snow cover has an important impact on the radiation balance of the Earth  
5 (Cohen and Rind, 1991). When light-absorbing particles (LAPs), such as black carbon  
6 (BC), organic carbon (OC), and mineral dust deposited on snow, can effectively reduce  
7 snow albedo (Hadley and Kirchstetter, 2012; He et al., 2017, 2018; Li et al., 2016;  
8 Warren, 1982, 1984; Warren and Wiscombe, 1980) and enhance the absorption of solar  
9 radiation (Dang et al., 2017; Kaspari et al., 2014; Liou et al., 2011, 2014; Painter et al.,  
10 2012b). Warren and Wiscombe (1980) indicated out that 10 ng g<sup>-1</sup> BC in old snow could  
11 reduce the snow albedo by nearly 1% at 400 nm with the snow grain size of 1000 μm.  
12 Based on model simulation, Jacobson (2004) pointed out that the snow albedo reduction  
13 caused by BC in snow and ice is 4% in the global and 1% in the Northern Hemisphere.  
14 LAPs in snow further contribute to alterations in snow morphology, accelerations in  
15 snowmelt, and reductions in snow cover (Flanner et al., 2007, 2009; Painter et al., 2013a;  
16 Xu et al., 2009). For example, Qian et al. (2009) simulated the deposition of BC on  
17 snow and its impact on snowpack and the hydrological cycle in the western United  
18 States and the results showed that BC-induced snow albedo perturbations caused a  
19 decrease of snow water equivalent by 2-50 mm over the mountains during late winter  
20 to early spring.  
21 Several studies have estimated the radiative forcing by LAPs in snow based on model  
22 simulations, which has nonnegligible effects on local hydrological cycles (Painter et al.,

1 2010; Qian et al., 2009; Yasunari et al., 2010) and regional and global climate (Bond et  
2 al., 2013; Hansen and Nazarenko, 2004; He et al., 2014; Jacobson, 2002, 2004;  
3 McConnell et al., 2007; Ramanathan and Carmichael, 2008; Yasunari et al., 2015). For  
4 example, in the Northern Hemisphere, Hansen and Nazarenko (2004) pointed out that  
5 the radiative forcing of BC on snow and ice albedo is  $+0.3 \text{ W m}^{-2}$ . In addition, the  
6 IPCC's AR5 (2013) indicated that the impact of BC in snow and ice accounted for a  
7 global mean climate forcing of  $+0.04 \text{ W m}^{-2}$ , but the confidence level is low. Bond et  
8 al. (2013) estimated the climate forcing consisting of radiative forcing, rapid  
9 adjustments, and the strong snow-albedo feedback due to BC-in-snow forcing and  
10 pointed that the best valuation of the climate forcing by BC in snow and sea ice is  $+0.13$   
11  $\text{W m}^{-2}$ , although the 90% uncertainty bounds are from  $+0.04 \text{ W m}^{-2}$  to  $+0.33 \text{ W m}^{-2}$ .  
12 Nevertheless, recent studies reported that ample factors confuse the model simulation  
13 of BC-in-snow induced climate forcing, and the model-based estimate of the regional  
14 and global radiative forcing caused by BC in snow and ice is still a challenge (Hansen  
15 and Nazarenko, 2004; Bond et al., 2013; Pu et al., 2017).

16 Much of northeastern China (NEC) is covered by contiguous seasonal snow in the  
17 winter and early spring. Local pollutant emissions in this region are some of the most  
18 intense in the world (Bond et al., 2004), leading to considerable amounts of LAPs  
19 deposited on snow (Bond et al., 2013). Several field campaigns have been conducted  
20 to analyze LAPs concentrations in snow across NEC (Huang et al., 2011; Wang et al.,  
21 2014a, 2015). Wang et al. (2013) conducted a large field campaign to measure LAPs in  
22 seasonal snow in northern China from January to February 2010. They found that BC

1 is the dominant absorber compared with OC and dust in NEC and BC concentrations  
2 in snow in this region range from 40 ng g<sup>-1</sup> to 4000 ng g<sup>-1</sup>, which are much higher than  
3 those measured in the Arctic, North America and Europe (Doherty et al., 2010, 2014;  
4 Peltoniemi et al., 2015). Recently, Wang et al. (2017) compared measured and  
5 simulated snow albedos and showed that LAPs can reduce the visible spectral albedo  
6 in NEC to 0.65, which indicated a significant impact of LAPs on snow albedo reduction.  
7 Zhao et al. (2014) simulated the radiative forcing by LAPs in snow over northern China  
8 using a coupled model; however, they noted that the uncertainties of their results are  
9 non-negligible, due to the limited observations that are available.

10 Remote sensing is considered to be a powerful tool for estimating snow physical  
11 properties (e.g., Nolin and Dozier, 1993, 2000) and LAPs-induced snow albedo  
12 reduction, which can provide valuable observational information for modeling studies  
13 to reduce modeling uncertainties. For instance, to estimate the influence of mineral dust  
14 on snow albedo in the European Alps, Di Mauro et al. (2015) defined a new spectral  
15 index, the Snow Darkening Index based on in situ measured snow spectral reflectance  
16 and the Landsat 8 Operational Land Imager (OLI) data, they found that the Snow  
17 Darkening Index could effectively track the content of mineral dust in snow. In addition,  
18 Di Mauro et al. (2017) characterized the impact of LAPs on ice and snow albedo of the  
19 Vadret da Morteratsch, a large valley glacier in the Swiss Alps using satellite (EO-1  
20 Hyperion) hyperspectral data. The results showed that the spatial distribution of both  
21 narrow-band and broad-band indices retrieved from Hyperion was related to ice and  
22 snow impurities. In the Arctic, Dumont et al. (2014) developed an Impurity Index based

1 on satellite observations (MODIS C5 surface reflectance) to analyze the snow  
2 darkening caused by the increased contents of LAPs in snow in Greenland.  
3 Nevertheless, Polashenski et al. (2015) pointed out that the apparent snow albedo  
4 decline in Greenland observed from MODIS C5 surface reflectance (Dumont et al.,  
5 2014) has a significant contribution from the uncorrected Terra sensor degradation. In  
6 this study, in order to prevent the interference from the sensor degradation, we used the  
7 latest version (version 6, C6) of MODIS data from Aqua sensor, which was verified to  
8 not suffer from the influence of sensor degradation (Polashenski et al., 2015). Even  
9 though these studies have confirmed the ability of remote sensing on assess the role of  
10 LAPs in snow on snow albedo reduction, however, they didn't quantitatively estimate  
11 the radiative forcing caused by LAPs in snow, which is extremely important for  
12 implying the impact of LAPs on regional and global climate. Recently, Painter et al.  
13 (2012a) have successfully used the MODIS Dust Radiative Forcing in Snow  
14 (MODDRFS) model to retrieve surface radiative forcing by LAPs in snow cover from  
15 Moderate Resolution Imaging Spectroradiometer (MODIS) surface reflectance data.  
16 They found that the instantaneous at-surface radiative forcing can beyond  $250 \text{ W m}^{-2}$   
17 in the Hindu Kush-Himalaya area and falls in a range of  $30\text{-}250 \text{ W m}^{-2}$  in the Upper  
18 Colorado River Basin. Painter et al. (2013b) also provided and validated an algorithm  
19 suite to quantitatively retrieve radiative forcing by LAPs in snow from Airborne  
20 Visible/Infrared Imaging Spectrometer (AVIRIS) data in the Senator Beck Basin Study  
21 Area (SBBSA), SW Colorado, USA. The lowest radiative forcing was found on the  
22 high north facing slopes while the highest on southeast facing slopes at the lowest

1 elevations. Seidel et al. (2016) analyzed the spatial and temporal distribution of  
2 radiative forcing by LAPs in snow in the Sierra Nevada and Rocky Mountain from  
3 imaging spectroscopy. Their results presented an increased radiative forcing from 20  
4  $\text{W m}^{-2}$  up to  $200 \text{ W m}^{-2}$  in the melting period. However, to date, no studies have  
5 quantitatively attributed the contributions of each factor to the variations of radiative  
6 forcing by LAPs in snow based on remote sensing. Moreover, no studies have estimated  
7 the radiative forcing by LAPs in snow across NEC using remote sensing, even though  
8 the LAP content is much higher compared with those in Arctic, Europe and USA (Dang  
9 et al., 2017).

10 In this study, we attempt to retrieve the radiative forcing by LAPs in snow across NEC  
11 using MODIS datasets combined with the Snow, Ice, and Aerosol Radiation (SNICAR)  
12 model (Flanner et al., 2007, 2009) and the Santa Barbara DISORT Atmospheric  
13 Radiative Transfer (SBDART) model (Ricchiuzzi et al., 1998), and estimate the  
14 uncertainties of radiative forcing from atmospheric correction and qualify the fractional  
15 contribution of each factor to the spatial variance of  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$ . Then, we will investigate  
16 the reasonability of the spatial patterns of retrieved radiative forcing in NEC based on  
17 BC deposition and snowfall data. Finally, we quantitatively estimate the biases of  
18 MODIS retrieved radiative forcing using in situ radiative forcing estimates, which are  
19 based on field measurements.

## 20 2. Datasets

### 21 2.1. Remote Sensing Datasets

22 The latest version (Collection 6) of MODIS surface reflectance data (MYD09GA),

1 MODIS snow cover data (MYD10A1), and MODIS aerosol optical depth (AOD) data  
2 (MYD04) are used in this study from 2003 to 2017 that cover the months of January  
3 through February (<https://modis.gsfc.nasa.gov/>). The MOD09 product is divided into 7  
4 bands (band 1, 620-670 nm; band 2, 841-876 nm; band 3, 459-479 nm; band 4, 545-  
5 565 nm; band 5, 1230-1250 nm; band 6, 1628-1652 nm; and band 7, 2105-2155 nm),  
6 and has a spatial resolution of 500 m (Vermote, 2015). The MOD09 surface reflectance  
7 is an estimate of the surface spectral reflectance for each band as it would have been  
8 measured at ground level as if there were no atmospheric scattering or absorption. It  
9 corrects for the effects of atmospheric gases and aerosols. The performance of the  
10 atmospheric correction algorithm suffers from the influence of view and solar zenith  
11 angles and aerosol optical thickness; the accuracy of the algorithm is also affected by  
12 the wavelengths of different bands. More details about the data product information and  
13 band quality description of MOD09GA could be found in the MODIS Surface  
14 Reflectance User's Guide (<https://modis.gsfc.nasa.gov/data/dataproduct/mod09.php>).  
15 MODIS satellite data has been widely accepted in retrieval of snow cover and its  
16 physical properties. (e.g. Scambos et al., 2007; Rittger et al., 2013). In addition, MODIS  
17 has three bands located in the visible bands (VIS) and radiometric range in the VIS over  
18 snow surface has no saturation phenomenon, which provide the ability of detecting the  
19 changes of reflectance in the VIS caused by LAPs in snow (Painter et al., 2012a).

## 20 2.2. Surface Measurement Datasets

21 Wang et al. (2017) conducted a snow survey across NEC in January 2014. They  
22 measured AOD using a Microtops II Sun photometer. The Microtops II Sun photometer

1 is a portable instrument and measures solar radiance in five spectral wave bands (340,  
2 440, 675, 870, and 936 nm) from which it automatically derives aerosol optical depth  
3 (AOD). When the Microtops II Sun photometer is well cleaned and well calibrated, its  
4 AOD retrievals can be comparable with those of CIMEL Sun photometers used in the  
5 AERONET network, with uncertainties ranging from 0.01 to 0.02 (Ichoku et al., 2002).  
6 The snow albedo and surface solar irradiance were measured using an Analytical  
7 Spectral Devices (ASD) spectroradiometer. The Analytical Spectral Devices Inc. (ASD)  
8 spectroradiometer has 3 nm spectral resolution on the visible/near infrared detector  
9 (350–1050 nm, silicon photodiode array), and 10–12 nm resolution on the short wave  
10 infrared detectors (900–2500 nm, InGaAs). Measurements are made by standing  
11 “down-sun” of the receptor, taking consecutive scans of downwelling and upwelling  
12 radiation. Wuttke et al. (2006) indicated that the ASD spectroradiometer is considered  
13 as the most mobile, capable, and rapid for measuring spectral albedo during short time  
14 periods, especially in very cold regions. The cosine error is less than 5% for solar zenith  
15 angles below 85° at a wavelength of 320 nm. We use these datasets to validate the snow  
16 grain size retrievals and the simulated surface solar irradiance values.

17 Snow samples were collected at 46 sites in January and February 2010 across Northern  
18 China (Wang et al., 2013) and at 13 sites in January 2014 across Northeastern China  
19 (Wang et al., 2017). A detailed description of the procedures of snow collection and  
20 filtration has been presented by previous studies (Doherty et al., 2010, 2014; Wang et  
21 al., 2013). Briefly, in order to keep the collected snow samples to be regionally  
22 representative and minimize the influence from the local emission sources, sample

1 locations were usually chosen at least 1 km upwind away from the approach roads and  
2 railways and more than 50 km from cities and towns. In addition, efforts were made to  
3 collect samples in open areas in order to prevent the contaminations from the detritus  
4 of bushes and trees. Generally, snow samples were collected within a vertical resolution  
5 varied from ~2 cm to 10 cm and usually at typically vertical intervals of 5 cm from the  
6 top to the bottom throughout the snowpack depth at each site. In a case of a visibly  
7 distinct layering, such as newly fallen snow at surface layer or a melt layer, the snow at  
8 that layer was gathered individually. Right and left snow samples of two side-by-side  
9 vertical profiles were collected within each layer to make a comparison and average the  
10 snow sample pairs. All snow samples were maintained frozen to prevent the melting  
11 snow from influencing the LAPs content. Usually every 3 to 4 days, snow samples were  
12 filtered at temporary laboratories set up in hotels. Simply, snow samples were melted  
13 and filtered through Nuclepore filters of 0.4  $\mu\text{m}$  pore size. The samples of “before” and  
14 “after” filtration were gathered and refrozen for the following chemical analysis, and  
15 the filters were used for optical analysis.

16 An integrating sphere/integrating sandwich spectrophotometer (ISSW) was applied to  
17 analyze the filters and quantify the spectral light absorption by LAPs in snow. ISSW  
18 was firstly described by Grenfell et al. (2011), modified by Wang et al. (2013) and  
19 Doherty et al. (2014), and has been used by some previous studies (Dang and Hegg,  
20 2014; 2014; Pu et al., 2017; Zhou et al., 2017). Schwarz et al. (2012) has confirmed the  
21 performance of ISSW in quantifying LAPs concentrations in snow by comparing with  
22 the Single Particle Soot Photometer (SP2) although both SP2 and ISSW may suffer

1 from non-negligible uncertainties. Briefly, ISSW produces a diffuse radiation field  
2 when white light illumination is transmitted into an integrating sphere, then the diffuse  
3 radiation pass through the filter from below and is measured by a spectrometer. By  
4 measuring a sample filter and a blank filter, respectively, ISSW acquires the light  
5 attenuation spectrum due to the loadings on sample filter (Grenfell et al., 2011).  
6 Because of the design that the measured filter is sandwiched between two integrating  
7 spheres, the light attenuation is nominally due to the absorption of LAPs on the filter  
8 and the influence of light scattering is negligible (Doherty et al., 2014). ISSW measures  
9 the light attenuation from 400 nm to 700 nm benefited from the optimal signal-to-noise  
10 ratio, and then extends the full spectral to a range of 350 to 750 nm by extrapolation  
11 (Pu et al., 2017). Calibration is done by measuring a set of fullerene (a synthetic BC,  
12 Alfa Aesar, Inc., Ward Hill, MA, USA) filters with a range of known loadings. Then,  
13 the light attenuation spectrum of the sample filter is transformed to an equivalent BC  
14 mass loading by against the standard filters. With the loaded area on the filter and the  
15 volume of filtered snow water, equivalent BC mass is converted to equivalent BC  
16 concentration ( $BC_{equiv}$ ). In this study, we will use  $BC_{equiv}$  on behalf of all LAPs to  
17 calculate the in situ radiative forcing.

### 18 2.3. BC Deposition and Snowfall Data

19 BC deposition and snowfall both have important effects on the radiative forcing by  
20 LAPs in snow (Seidel et al., 2016). Higher BC deposition indicates that greater amounts  
21 of BC are deposited on snow, reducing the snow albedo. A higher frequency of snowfall  
22 implies that greater amounts of fresh snow, which has smaller snow grains than aged

1 snow, are present at the surface, increasing the snow albedo (Wang et al., 2014b).

2 Therefore, we examine the retrieved results based on the snowfall data in January-

3 February from 2003 to 2017 from the ERA-Interim reanalysis

4 (<http://apps.ecmwf.int/datasets/data/interim-full-daily/levtype=sfc/>), and the BC dry

5 and wet deposition data of MIROC5 historical experiments from phase 5 of the Coupled

6 Model Intercomparison Project in January-February from 2003 to 2005 (CMIP5;

7 Taylor et al., 2012).

8 3. Methods

9 3.1. Models

10 3.1.1. SNICAR model

11 Snow, Ice, and Aerosol Radiative (SNICAR) model is the most widely used multi-layer

12 snow albedo model in the fields of atmospheric sciences. Flanner et al. (2007) has

13 presented a comprehensive description for SNICAR model. Here, we just briefly give

14 a summary of SNICAR. SNICAR simulates radiative transfer in snowpack based on

15 the theory of Wiscombe and Warren (1980) and the two-stream multilayer radiative

16 approximation of Toon et al (1989). The input optical parameters (mass extinction

17 coefficient, single scatter albedo, and asymmetry factors) of snow grains and LAPs are

18 off-line calculated using Mie theory. In addition, the types of surface spectral

19 distribution (clear- or cloudy-sky) and incident radiation (direct or diffuse) can be

20 chosen by users, and users must specify the solar zenith angle if the incident flux is

21 direct. In general, users should input the parameters involving the type of surface

22 spectral distribution and incident radiation, number of snow layers, snow thickness,

1 density, snow grain radius, and the type and concentration of LAPs in each snow layer,  
2 the albedo of underlying ground, Following the previous study (Painter et al., 2012a),  
3 we assume one-layer semi-infinite snow to drive SNICAR model in this study.

#### 4 3.1.2. SBDART model

5 In this study, we use the Santa Barbara DISORT Atmospheric Radiative Transfer  
6 (SBDART) model (Ricchiuzzi et al., 1998) to simulate the surface solar irradiance.  
7 SBDART is one of the most widely used models to calculate the radiative transfer at  
8 the Earth's surface and within the atmosphere in both clear and cloudy sky. SBDART  
9 is a combination of a DISORT (Discrete Ordinate Radiative Transfer) radiative transfer  
10 module (Stamnes et al., 1988), low-resolution atmospheric transmission models, and  
11 Mie theory. The radiative transfer equations for a plane-parallel, vertically  
12 inhomogeneous, non-isothermal atmosphere numerically integrated in SBDART are  
13 based on DISORT and light scattering by water droplets and ice crystals results from  
14 Mie theory. SBDART already considers all important processes that affect the  
15 ultraviolet, visible, and infrared radiation fields. The key components of SBDART  
16 include standard atmospheric models, cloud models, extraterrestrial source spectra, gas  
17 absorption models, standard aerosol models, and surface models. SBDART is well  
18 suitable for a widespread use in atmospheric radiation and remote sensing studies. More  
19 details about SBDART model could be found in the paper of Stamnes et al. (1988).

#### 20 3.2. Retrieval Methods

21 In this study we use BC as a representative to describe the effect of LAPs on snow  
22 albedo. Figure 1a shows the spectral snow albedo from 300 to 1400 nm. Gray areas

1 show the typical spectral solar irradiance at the time of MODIS Aqua overpass (local  
2 time of 1:30 PM) in January-February of NEC; the yellow column bars represent  
3 MODIS bandpasses. We can see that when LAPs such as BC deposited on snow, can  
4 effectively reduce snow albedo in the visible bands, which contain about half of total  
5 solar radiation. For a snowpack with snow grains radius of 100-300  $\mu\text{m}$ , 100  $\text{ng g}^{-1}$  BC  
6 in snow (a typical BC concentration in snow of the remote clean areas in NEC) can  
7 reduce snow albedo of  $\sim 0.05$ - $0.08$  at 500 nm; 1000  $\text{ng g}^{-1}$  BC in snow (a typical BC  
8 concentration in snow of the polluted industrial areas in NEC) can reduce snow albedo  
9 of  $\sim 0.12$ - $0.2$ . On the other hand, the effects of BC decrease at longer wavelengths in  
10 the near infrared (NIR). Moreover, when wavelengths exceed 1150 nm, snow albedo is  
11 dominated by the snow optical effective radius ( $R_{\text{eff}}$ ) and is independent of LAPs. As  
12 shown in Figure 1b, snow albedo reduction is not only dependent on LAPs in snow but  
13 also snow grains size and solar zenith angle ( $\theta$ ). Generally, the reduction in snow albedo  
14 caused by BC increases with BC concentration and  $R_{\text{eff}}$ , whereas it decreases with the  
15 solar zenith angle ( $\theta$ ). Based on these characteristics, we retrieve  $R_{\text{eff}}$ , the reduction in  
16 snow albedo, and the radiative forcing by LAPs in this section.

### 17 3.2.1. Snow Cover

18 Three methods have been widely used in mapping snow-covered area using MODIS  
19 data. In the first method, “binary” maps, pixels are classified as either “snow-free” or  
20 “snow-covered” (Hall et al., 1995). However, significant errors exist in such maps, as  
21 pixels with a resolution of 500 m are not always completely covered by snow. The  
22 second method, the MODSCAG retrieval algorithm, is a fractional snow algorithm that

1 is based on spectral mixture analysis (Painter et al., 2009). However, it cannot be  
2 applied in NEC, due to limited information on the spectral reflectances of the vegetation,  
3 soils and rock in this region. Therefore, we use the third method, which is based on the  
4 reflectances in the visible bands and the normalized difference snow index (NDSI):

$$5 \quad \text{NDSI} = \frac{R_{\text{band4}} - R_{\text{band6}}}{R_{\text{band4}} + R_{\text{band6}}} \quad (1)$$

6 where  $R_{\text{band4}}$  and  $R_{\text{band6}}$  are the surface reflectances in bands 4 and 6. Following Negi  
7 and Kokhanovsky (2011), an area is determined to be snow-covered if the NDSI and  
8 the reflectance in band 4 both exceed 0.6. We note that the following analysis are only  
9 done over the defined snow covered areas and periods.

### 10 3.2.2. Retrieval of Snow Grain Size

11 Many methods have been used to retrieve snow grain size (e.g., Lyapustin et al., 2009;  
12 Nolin and Dozier, 1993). However, in NEC, the efficacy of most of these methods is  
13 limited, as the reflectances in bands 1-4 are seriously affected by LAPs in polluted snow  
14 (Figure 1a), and the reflectances in bands 6-7 are not sensitive to  $R_{\text{eff}}$ . Hence,  $R_{\text{eff}}$  is  
15 retrieved at a wavelength of 1240 nm (the central wavelength of band 5) using SNICAR  
16 (Wang et al., 2017).

17 We validate the retrieved  $R_{\text{eff}}$  values using in situ measurements. The mean absolute  
18 error (MAE) is 71  $\mu\text{m}$ , which is slightly higher than that reported by Painter et al. (2009).  
19 Nevertheless, the results are still credible because this study investigates a larger spatial  
20 scale than the previous study.

### 21 3.2.3. Impurity Index

22 To assess LAP contents in snow, we use the surface reflectances in bands 4-5 to derive

1 an impurity index ( $I_{LAPs}$ ):

$$2 \quad I_{LAPs} = \frac{\ln(R_{band4})}{\ln(R_{band5})} \quad (2)$$

3 This quantity increases with the LAP content but is almost independent of  $R_{eff}$  and  $\theta$

4 (Figure 1c). Di Mauro et al. (2017) has successfully exhibited  $I_{LAPs}$  to assess the

5 variations of LAP contents in the snow of the Morteratsch Glacier in the Swiss Alps.

6 In this study, we didn't retrieve the concentrations of LAPs. Because such retrieval is

7 constrained by many unknown factors, such as size distribution, optical properties and

8 the mixing state of LAPs (He et al., 2017, 2018; Painter et al., 2013a; Pu et al., 2017).

9 Therefore, the conversion from satellite spectra to ground concentrations of LAPs will  
10 cause significant errors.

#### 11 3.2.4. Retrieval of Radiative Forcing by LAPs in Snow

12 Instantaneous surface solar irradiance at the time of MODIS overpass in January-

13 February is simulated using the SBDART model (Ricchiuzzi et al., 1998) with MODIS

14 AOD data as inputs. Wang et al. (2017) has validated the MODIS AOD data using in

15 situ measurements in NEC. For the other inputs, the typical values for mid-latitude

16 winter provided by SBDART are used. As a result, the normalized mean bias (NMB)

17 is less than 2% (Figure S1).

18 We estimate the instantaneous spectrally-integrated radiative forcing at the surface by

19 LAPs in snow ( $RF_{MODIS}^{LAPs}$ ) under clear-sky conditions at the time of MODIS Aqua

20 overpass, which is a function of solar irradiance and the difference between the MODIS

21 spectral reflectance and a simulated clean-snow ( $R_{\lambda}^{clean-snow}$ ) reflectance (Miller et al.,

22 2016).  $R_{\lambda}^{clean-snow}$  is simulated using SNICAR model based on the retrieved  $R_{eff}$  and

1 MODIS derived solar zenith angle ( $\theta$ ). On the other hand, for MODIS spectral  
2 reflectance, because MODIS provides only discrete reflectances, we simulate a  
3 continuous spectral reflectance by fitting SNICAR to the MODIS data and derive the  
4 fitting parameters by minimizing the RMSE (Painter et al., 2009):

$$5 \quad \text{RMSE} = \left( \frac{1}{4} \sum_{\lambda=\text{band1}}^{\text{band4}} (R_{\lambda}^{\text{model}} - R_{\lambda}^{\text{MODIS}})^2 \right)^{1/2} \quad (3)$$

6 where RMSE is the root mean squared error; and  $R_{\lambda}^{\text{model}}$  and  $R_{\lambda}^{\text{MODIS}}$  represent the  
7 simulated and MODIS-derived reflectances at a wavelength  $\lambda$ . Thus,  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$  is  
8 expressed as follows:

$$9 \quad \text{RF}_{\text{MODIS}}^{\text{LAPs}} = \sum_{\lambda=300 \text{ nm}}^{1240 \text{ nm}} E_{\lambda} * D_{\lambda} * \Delta\lambda \quad (4)$$

10 where  $E_{\lambda}$  is the solar irradiance at a wavelength  $\lambda$  simulated by SBDART model;  $D_{\lambda}$   
11 is the difference between the clean-snow ( $R_{\lambda}^{\text{clean-snow}}$ ) and simulated reflectances ( $R_{\lambda}^{\text{model}}$ )  
12 at a wavelength  $\lambda$ ; and  $\Delta\lambda$  is 10 nm.

### 13 3.2.5. Uncertainties

14 The uncertainties in radiative forcing retrievals are primarily due to terrain, liquid snow  
15 water, snow patchiness, protrusion of vegetation and atmospheric correction. The study  
16 areas are located on smooth plains, and the content of liquid snow water is limited in  
17 the study regions in January and February (Wang et al., 2013). Moreover, both  
18 experimental and theoretical evidences show that the effect of liquid water in snow on  
19 snow reflectance is small in the shortwave part of the spectrum but obvious at the  
20 wavelengths of 0.95  $\mu\text{m}$  and 1.15  $\mu\text{m}$  (O'Brien and Munis, 1975; O'Brien and Koh,  
21 1981; Wiscombe and Warren 1980), which are not included in MODIS bands used in

1 our study. As a result, the effect of liquid water in snow on the calculations of snow  
2 grain size,  $I_{LAPs}$  and radiative forcing are limited. Therefore, the effects of terrain and  
3 liquid snow water on MODIS retrievals could be negligible.

4 In our study, the snow-covered area is determined if the NDSI and the reflectance in  
5 band 4 both exceed 0.6, which means that fractional snow cover (FSC) is larger than  
6 0.87 according to the FSC equation ( $FSC = -0.01 + 1.45 * NDSI$ ) from the MODIS Snow  
7 Products Collection 6 User Guide (<http://nsidc.org/data/MYD10A1>). In January and  
8 February, snow depth is much high and reaches its maximum depth in NEC, snow  
9 patchiness in high snow-covered areas is mostly due to the protrusion of vegetation  
10 according to the observations of field campaigns (Wang et al., 2013, 2014a). So that  
11 the MODIS derived surface reflectance ( $R_{\lambda}^{MODIS}$ ) in a pixel of our study areas is not  
12 snow reflectance, but a mixture of snow and vegetation reflectance. Therefore, we need  
13 to correct the errors of snow reflectance caused by the protrusion of vegetation.

14 According to Painter et al. (2009),  $R_{\lambda}^{MODIS}$  could be expressed as:

$$15 \quad R_{\lambda}^{MODIS} = \frac{E_{\lambda} * FSC * R_{snow}^{\lambda} + E_{\lambda} * (1 - FSC) * R_{vegetation}^{\lambda}}{E_{\lambda}}$$
$$16 \quad = FSC * R_{snow}^{\lambda} + (1 - FSC) * R_{vegetation}^{\lambda} \quad (5)$$

17 where  $R_{\lambda}^{MODIS}$  is MODIS derived surface reflectance at a wavelength  $\lambda$ ,  $E_{\lambda}$  is solar  
18 irradiance at a wavelength  $\lambda$ . FSC is the fractional snow cover, which could be derived  
19 according to the FSC equation.  $R_{snow}^{\lambda}$  and  $R_{vegetation}^{\lambda}$  represent snow and vegetation  
20 reflectance, respectively, at a wavelength  $\lambda$ .  $R_{vegetation}^{\lambda}$  is from the study of Siegmund  
21 and Menz (2005). Then  $R_{snow}^{\lambda}$  could be expressed as:

$$R_{\text{snow}}^{\lambda} = \frac{(R_{\lambda}^{\text{MODIS}} - (1 - \text{FSC}) * R_{\text{vegetation}}^{\lambda})}{\text{FSC}} \quad (6)$$

Finally, the accuracy of MODIS surface reflectance (MYD09GA) due to atmospheric correction is typically calculated based on the MODIS Surface Reflectance User's Guide (Collection 6, <https://modis.gsfc.nasa.gov/data/dataproduct/mod09.php>) as follows:

$$\pm (0.005 + 0.05 * \text{reflectance})$$

which is suitable under conditions that AOD is less than 5.0 and  $\theta$  is less than  $75^{\circ}$ . Therefore, we also estimate the uncertainty of MODIS retrievals from atmospheric correction. Briefly, the MODIS derived snow reflectance ( $R_{\text{snow, uncertainty}}^{\lambda}$ ), which takes into an account of the accuracy of the atmospheric correction, is expressed as:

$$R_{\text{snow, uncertainty}}^{\lambda} = R_{\text{snow}}^{\lambda} \pm (0.005 + 0.05 * R_{\text{snow}}^{\lambda}) \quad (7)$$

then, the fractional uncertainty of MODIS retrieved snow grain size ( $\text{FU}_{R_{\text{eff}}}$ ) could be expressed as:

$$\text{FU}_{R_{\text{eff}}} = \frac{R_{\text{eff, uncertainty}} - R_{\text{eff}}}{R_{\text{eff}}} \quad (8)$$

where  $R_{\text{eff, uncertainty}}$  is the SNICAR simulated snow grain size using the snow reflectance of  $R_{\text{snow, uncertainty}}^{1240}$ . Similar to snow grain size, the fractional uncertainty of

$I_{\text{LAPs}}$  ( $\text{FU}_{I_{\text{LAPs}}}$ ) and  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$  ( $\text{FU}_{\text{RF}}$ ) is:

$$\text{FU}_{I_{\text{LAPs}}} = \frac{I_{\text{LAPs, uncertainty}} - I_{\text{LAPs}}}{I_{\text{LAPs}}} \quad (9)$$

$$\text{FU}_{\text{RF}} = \frac{\text{RF}_{\text{MODIS, uncertainty}}^{\text{LAPs}} - \text{RF}_{\text{MODIS}}^{\text{LAPs}}}{\text{RF}_{\text{MODIS}}^{\text{LAPs}}} \quad (10)$$

We note that the positive and negative uncertainty is asymmetric due to the nonlinearity of SNICAR model.

3.2.6. Attribution of the Spatial Variance of Radiative Forcing by LAPs in Snow

1 As discussed above,  $RF_{MODIS}^{LAPs}$  is dependent on  $I_{LAPs}$ ,  $R_{eff}$  and  $\theta$ , and could be  
 2 expressed as:

$$3 \quad RF_{MODIS}^{LAPs} = f(I_{LAPs}, R_{eff}, \theta) \quad (11)$$

4 as a result, the spatial patterns of  $I_{LAPs}$ ,  $R_{eff}$  and  $\theta$  determine the spatial pattern of  
 5  $RF_{MODIS}^{LAPs}$ . Firstly, we keep  $R_{eff}$  and  $\theta$  spatially constant with values of the spatial  
 6 averages ( $\overline{R_{eff}}$  and  $\overline{\theta}$ ). Therefore, the spatial pattern of radiative forcing is only  
 7 dependent on the distribution of  $I_{LAPs}$ :

$$8 \quad RF_{MODIS}^{LAPs}(I_{LAPs}) = f(I_{LAPs}, \overline{R_{eff}}, \overline{\theta}) \quad (12)$$

9 similarly, we could obtain another two equations:

$$10 \quad RF_{MODIS}^{LAPs}(R_{eff}) = f(\overline{I_{LAPs}}, R_{eff}, \overline{\theta}) \quad (13)$$

$$11 \quad RF_{MODIS}^{LAPs}(\theta) = f(\overline{I_{LAPs}}, \overline{R_{eff}}, \theta) \quad (14)$$

12 Then  $RF_{MODIS}^{LAPs}$  is regressed with  $RF_{MODIS}^{LAPs}(I_{LAPs})$ ,  $RF_{MODIS}^{LAPs}(R_{eff})$  and  $RF_{MODIS}^{LAPs}(\theta)$  using  
 13 multiple linear regression, the regressed radiative forcing ( $RF_{Regression}^{LAPs}$ ) is expressed as:

$$14 \quad RF_{Regression}^{LAPs} = a + b * RF_{MODIS}^{LAPs}(I_{LAPs}) + c * RF_{MODIS}^{LAPs}(R_{eff}) + d * RF_{MODIS}^{LAPs}(\theta) \quad (15)$$

15 where a, b, c and d are regression coefficients. In our study, we find that  $RF_{Regression}^{LAPs}$   
 16 could explained 99.9% of the variance of  $RF_{MODIS}^{LAPs}$  (Figure S2). Therefore, we can  
 17 attribute the variance of  $RF_{Regression}^{LAPs}$  instead of  $RF_{MODIS}^{LAPs}$  to estimate the fractional  
 18 contribution of  $I_{LAPs}$ ,  $R_{eff}$  and  $\theta$  to radiative forcing. Equation 15 can be written as:

$$19 \quad RF_{Regression}^{LAPs} - \overline{RF_{Regression}^{LAPs}} = b * (RF_{MODIS}^{LAPs}(I_{LAPs}) - \overline{RF_{MODIS}^{LAPs}(I_{LAPs})}) + c * (RF_{MODIS}^{LAPs}(R_{eff}) - \overline{RF_{MODIS}^{LAPs}(R_{eff})}) + d * (RF_{MODIS}^{LAPs}(\theta) - \overline{RF_{MODIS}^{LAPs}(\theta)}) \quad (16)$$

21 where,  $RF_{Regression}^{LAPs} - \overline{RF_{Regression}^{LAPs}}$  is radiative forcing anomaly ( $RF_{Regression, anomaly}^{LAPs}$ ). Then,

22 Equation 16 can be written as:

$$\begin{aligned}
 1 \quad \text{RF}_{\text{Regression, anomaly}}^{\text{LAPs}} &= \text{b} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\text{I}_{\text{LAPs}}) + \text{c} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\text{R}_{\text{eff}}) + \\
 2 \quad &\quad \text{d} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\theta) \quad (17)
 \end{aligned}$$

3 according to Huang et al. (2016) and Huang and Yi (1991), the fractional contribution  
 4 of  $\text{I}_{\text{LAPs}}$  to the variance of radiative forcing ( $\text{FC}_{\text{I}_{\text{LAPs}}}$ ) can be expressed as:

$$\begin{aligned}
 5 \quad \text{FC}_{\text{I}_{\text{LAPs}}} &= \\
 6 \quad \frac{1}{m} \sum_{i=1}^m &\left( \frac{(\text{b} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\text{I}_{\text{LAPs}})_i)^2}{(\text{b} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\text{I}_{\text{LAPs}})_i)^2 + (\text{c} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\text{R}_{\text{eff}})_i)^2 + (\text{d} * \text{RF}_{\text{MODIS, anomaly}}^{\text{LAPs}} (\theta)_i)^2} \right) \\
 7 \quad &\quad (18)
 \end{aligned}$$

8 where, m is the length of the data series. Similarly, we can obtain  $\text{FC}_{\text{R}_{\text{eff}}}$  and  $\text{FC}_{\theta}$ .

### 9 3.2.7. Calculation of In situ Radiative Forcing by LAPs in Snow

10  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$  should be validated with measurements. However, due to the lack of radiative  
 11 forcing measurements in NEC, we estimate the in situ radiative forcing ( $\text{RF}_{\text{in situ}}^{\text{estimated}}$ ) from  
 12 measured  $\text{BC}_{\text{equiv}}$  values. Briefly, we use SNICAR to calculate the in situ reduction in  
 13 snow albedo from  $\text{BC}_{\text{equiv}}$  and MODIS retrieved  $\text{R}_{\text{eff}}$ . Then, the SBDART model is  
 14 used to estimate  $\text{RF}_{\text{in situ}}^{\text{estimated}}$ .

## 15 4. Results

### 16 4.1. The spatial distribution of AOD and BC emission

17 Northeastern China suffers from heavy local pollutant emissions with high aerosol mass  
 18 concentrations in winter (Wiedensohler et al., 2009). Figure 2a shows the spatial  
 19 distribution of AOD at 550 nm derived from MODIS in NEC. We can find that AOD  
 20 in the studying areas range from 0.08 to 0.65 and show strong spatial inhomogeneity.  
 21 The largest AOD values are found in industrial areas at the south central of NEC, where

1 are the largest urban areas of NEC with the major cities of Harbin, Changchun, and  
2 Shenyang. These areas are associated with the largest pollution emission and  
3 anthropogenic activities in NEC (Wang et al., 2017). By comparison, the MODIS-Aqua  
4 results show that the AOD in the west of NEC along the border of China is smallest.  
5 Similar patterns of AOD were also found by Zhang et al. (2013) and Zhao et al. (2014).  
6 Previous studies indicated that BC are the primary light-absorbing particles in  
7 atmosphere (Cao et al., 2006) and seasonal snow (Wang et al., 2013). Figure 2b shows  
8 the spatial distribution of BC emission density in January-February of 2010 in NEC.  
9 The pattern of BC emission density is very comparable to AOD with the highest values  
10 of  $> 5 \cdot 10^4 \text{ g km}^{-2} \text{ month}^{-1}$  in south central NEC and the lowest values of  $< 5 \cdot 10^2 \text{ g km}^{-2}$   
11  $\text{month}^{-1}$  in the remote areas of northwestern China. Both the results of AOD and BC  
12 emission density imply that the seasonal snow in south central of NEC suffers from  
13 abundant BC deposition and the radiative forcing by LAPs in snow is likely to be  
14 highest in NEC.

#### 15 4.2. The spatial distribution of snowfall frequency and land cover types

16 Snowfall is spatially varied in NEC and has a dominated effect on local fractional snow  
17 cover, then defined snow-covered areas, where we retrieved the radiative forcing by  
18 LAPs in snow in our study. Figure 3a shows the normalized snowfall frequency in  
19 January-February from 2003 to 2017. We can find that the highest snowfall frequency  
20 occurred in northwestern and southeastern NEC, where are forest-covered areas (see  
21 Figure 3b). In contrast, the areas from central to southwestern NEC present lowest  
22 snowfall frequency, which means that the fractional snow cover in these areas is likely

1 to be lower than other areas and unable to reach to the critical value that we used to  
2 define the snow-covered areas. On the other hand, land cover types will also affect the  
3 local fractional snow cover. From Figure 3b, we can find that NEC presents a spatially  
4 different land cover types, the main land cover types are grasslands, croplands and  
5 evergreen needle leaf (forests). Grasslands and croplands are mainly located in  
6 southwestern NEC and central NEC respectively, while forests are distributed in  
7 northern and southeastern NEC. In our study periods, grasslands and croplands have  
8 limited influence on snow cover. However, in forest areas, even completed covered by  
9 deep snow, forest will effectively affect the derived surface reflectance from MODIS-  
10 Aqua satellite, then the determination of snow-covered areas (further discussions in  
11 Section 5).

#### 12 4.3. Radiative Forcing by LAPs in Snow

13 Figure 4 shows the identified snow-covered areas, which are primarily concentrated  
14 between 40 °N and 50 °N. Consistent with our analysis above, the low snow-frequency  
15 areas of south central and southwestern NEC and forest-covered areas of northern and  
16 southeastern NEC are not identified as snow-covered areas. According to the  
17 geographical distribution (Figure 4a), we separated the studied areas into three regions:  
18 western NEC (WNEC), central NEC (CNEC) and eastern NEC (ENEC).

19 The spatial distributions of  $I_{LAPs}$ ,  $R_{eff}$ , and  $RF_{MODIS}^{LAPs}$  are displayed in Figure 4, and  
20 their statistics are presented in Figure 5. On average,  $I_{LAPs}$  is  $\sim 0.27 \pm 0.045$ ;  $R_{eff}$  is  
21  $\sim 261 \pm 32 \mu m$ ; and  $RF_{MODIS}^{LAPs}$  is  $\sim 45.1 \pm 6.8 \text{ W m}^{-2}$  in NEC. Regionally,  $RF_{MODIS}^{LAPs}$  is  
22 largest and shows an average of  $\sim 50.9 \pm 4.2 \text{ W m}^{-2}$  in CNEC, where is located in the

1 industrial areas and closed to the largest urban areas of NEC, therefore suffers from the  
2 most serious pollutant emissions among these three regions. ENEC displays the second  
3 largest radiative forcing with an average  $RF_{MODIS}^{LAPs}$  of  $\sim 45.7 \pm 4.5 \text{ W m}^{-2}$ . The lowest  
4 value of  $\sim 41.0 \pm 5.9 \text{ W m}^{-2}$  occurs in WNEC, where both AOD and BC emission density  
5 are lowest compared with other two regions, which is not only due to the low local  
6 pollutant emissions but also because that the regional transport of this region in our  
7 study period is mostly from the clean northwest and suffer from little influence of  
8 human activities (Wang et al., 2014b). For the individual regions,  $RF_{MODIS}^{LAPs}$  presents an  
9 increase from north to south in CNEC that ranges from 40.4 to 64.6  $\text{W m}^{-2}$ . In ENEC  
10 an east-west gradient of  $RF_{MODIS}^{LAPs}$  is noted that ranges from 62.0 to 35.0  $\text{W m}^{-2}$ . The  
11 most distinct intra-regional difference is in WNEC, where  $RF_{MODIS}^{LAPs}$  ranges from 22.3  
12  $\text{W m}^{-2}$  to 55.5  $\text{W m}^{-2}$ . Generally, the patterns are consistent with those of AOD and BC  
13 emission density in NEC. Moreover, the spatial pattern of radiative forcing by LAPs in  
14 snow in this study is comparable with the results by Zhao et al. (2014), who firstly  
15 estimated the radiative forcing of LAPs in snow through WRF model and found that  
16 the radiative forcing in industrial source regions such as southern CNEC is obviously  
17 much higher than that in border regions such as WNEC, which primarily resulted from  
18 the spatial differences of LAP dry and wet deposition. Compared with the results from  
19 other studies, Seidel et al. (2016) reported a radiative forcing of  $\sim 20 \text{ W m}^{-2}$  in the Sierra  
20 Nevada in late February, which is lower than the result in NEC, eventhough the surface  
21 solar irradiance in Sierra Nevada is higher. Painter et al. (2013b) reported an average  
22 radiative forcing of  $215 \pm 63 \text{ W m}^{-2}$  in the Senator Beck Basin Study Area (SBBSA),

1 SW Colorado, USA, which is approximately four times of our retrieved radiative  
2 forcing near industrial areas in NEC. However, the snow grain size and the surface solar  
3 irradiance in their study period is larger than that in our study by a factor of  $>2.5$  and  $>4$ ,  
4 respectively. The results implied the abundant LAP content in snow of CNEC. The  
5 regional and intra-regional patterns of variability in  $I_{LAPs}$  are quite similar to those of  
6  $RF_{MODIS}^{LAPs}$ , which indicates the significant role of LAP content in determining the spatial  
7 distribution of radiative forcing; the average values of  $I_{LAPs}$  are  $\sim 0.311 \pm 0.024$  in  
8 CNEC,  $\sim 0.307 \pm 0.026$  in ENEC, and  $\sim 0.238 \pm 0.031$  in WNEC. In contrast to  $I_{LAPs}$  and  
9  $RF_{MODIS}^{LAPs}$ ,  $R_{eff}$  displays a smaller spatial variance and presents average values of  $\sim 285$   
10  $\pm 16 \mu m$ ,  $\sim 281 \pm 15 \mu m$ , and  $\sim 239 \pm 29 \mu m$  in CNEC, ENCE and WNEC, respectively.  
11  $R_{eff}$  in WNEC is a little smaller compared with those in other two regions, which is  
12 probably due to the higher snowfall frequency, because higher snowfall frequency  
13 indicates longer duration of fresh finer snow at surface (Wang et al., 2013; Seidel et al.,  
14 2016).

15 Figure 6 shows the average uncertainties of  $I_{LAPs}$ ,  $R_{eff}$  and  $RF_{MODIS}^{LAPs}$  due to  
16 atmospheric correction in NEC in January-February from 2003 to 2017. The positive  
17 (negative) uncertainties of retrieved  $I_{LAPs}$  and  $RF_{MODIS}^{LAPs}$  from atmospheric correction  
18 are comparable and range from 9% to 43% (-10% to -47%) and 14% to 57% (-14% to  
19 -47%), respectively. Both of  $I_{LAPs}$  and  $RF_{MODIS}^{LAPs}$  show larger uncertainties as their  
20 values are smaller; the positive (negative) uncertainties of  $I_{LAPs}$  and  $RF_{MODIS}^{LAPs}$  are  
21 largest in WNEC and show averages of 21% (-24%) and 30% (-28%), while the lowest  
22 uncertainties of 13% (-15%) and 20% (-20%) for  $I_{LAPs}$  and  $RF_{MODIS}^{LAPs}$  are found in

1 CNEC. It is because that the uncertainty of snow albedo from atmospheric correction  
2 is almost similar in our study areas across the whole NEC region as discussed in Section  
3 3.6, however the snow albedo reduction is smaller in clean snow and larger in polluted  
4 snow, which results into a larger relative uncertainty of snow albedo reduction in clean  
5 snow and a smaller relative uncertainty in polluted snow according to Equation 8. The  
6 positive (negative) uncertainties of  $R_{\text{eff}}$  are smaller compared with  $I_{\text{LAPs}}$  and  
7  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$ , and range from 14 to 18% (-12% to -16%), which is comparable with the errors  
8 between MODIS retrieved and in situ measured snow grain size discussed in Section  
9 3.2.2. Moreover, the uncertainties are spatially quite consistent for  $R_{\text{eff}}$ , which is  
10 different from  $I_{\text{LAPs}}$  and  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$ . We note that the positive and negative uncertainties  
11 of all  $I_{\text{LAPs}}$ ,  $R_{\text{eff}}$ , and  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$  are asymmetric, which are primarily due to the  
12 nonlinear characteristics of the radiative transfer in SNICAR model (Painter et al.,  
13 2007).

14 As discussed in Section 3, the spatial distribution of  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$  depends on  $I_{\text{LAPs}}$ ,  $R_{\text{eff}}$   
15 and  $\theta$ . Even though some studies have successfully retrieved the radiative forcing by  
16 LAPs in snow using remote sensing (e.g. Painter et al., 2012a, 2013b). However, none  
17 of them has quantitatively estimate what degree of certainty can the variations of  
18 radiative forcing be attributed to LAPs in snow. Then we would like to qualify the  
19 contribution of each factor to the spatial variance of  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$ . Combing sensitive test  
20 and the method of Huang and Yi (1991) as discussed in 3.2.6, we estimate the fractional  
21 contribution of  $I_{\text{LAPs}}$ ,  $R_{\text{eff}}$  and  $\theta$  to the spatial variance of  $\text{RF}_{\text{MODIS}}^{\text{LAPs}}$  in our study areas  
22 across NEC (Figure 7). We can find that the contributions from LAPs is largest with a

1 value of 74.6%, while  $R_{\text{eff}}$  and  $\theta$  make contributions of 21.2% and 4.2%, respectively  
2 in NEC. The result indicates that the LAP content in snow plays a dominant role in  
3 determining the spatial distribution of  $RF_{\text{MODIS}}^{\text{LAPs}}$ . Regionally, the contribution of LAPs  
4 in WNEC (62.1%) is smaller than those of 73.9% and 83.4% in CNEC and ENEC,  
5 while  $R_{\text{eff}}$  shows a higher contribution of 28.1% in WNEC than those of 19.6% and  
6 13.9% in CNEC and ENEC. The results point out a less important effect of LAPs but  
7 more important effect of  $R_{\text{eff}}$  on the spatial distribution of  $RF_{\text{MODIS}}^{\text{LAPs}}$  in WNEC  
8 compared with those in CNEC and ENEC. In addition, the contribution of  $\theta$  is smaller  
9 in ENCE (2.7%) than those of 9.8% and 6.5% in WNEC and CNEC, which is primary  
10 due to the smallest altitude range of ENEC among those three regions.

11 Seidel et al. (2016) reported that the variations in LAP contents in snow are dominated  
12 by LAP deposition and snowfall. Previous studies have also reported that BC is the  
13 dominant LAP type in NEC (Wang et al., 2013). Zhao et al. (2014) simulated LAP  
14 content and their radiative forcing in seasonal snow using WRF-Chem coupled with  
15 SNICAR model and indicated that the radiative forcing by LAPs in snow in NEC is  
16 primarily due to BC. Therefore, to examine the spatial distributions of retrieved  $I_{\text{LAPs}}$   
17 and  $RF_{\text{MODIS}}^{\text{LAPs}}$ , we display the distribution of snowfall (Figure 3a) and BC dry and wet  
18 deposition (Figure 8). BC dry deposition is highest in the largest urban areas of NEC  
19 with the major cities of Harbin, Changchun, and Shenyang, then decrease sharply  
20 outwards from the central of urban areas to remote areas (Figure 8a). Different from  
21 BC dry deposition, which is dominated by BC concentrations in the atmosphere, BC  
22 wet deposition is affected by both BC concentrations and precipitation and shows an

1 increase from northwest to southeastern. Generally, the spatial patterns of BC dry and  
2 wet deposition are similar with  $I_{LAPs}$  and  $RF_{MODIS}^{LAPs}$ . For example, areas with higher BC  
3 dry and wet deposition such as industrial polluted NEC show higher  $I_{LAPs}$  and  
4  $RF_{MODIS}^{LAPs}$ . Moreover, from Figure 9a-c, we can find that the correlations between  $I_{LAPs}$   
5 with BC dry and wet deposition and snowfall ( $R^2=0.65, 0.71, \text{ and } 0.19$ ) are significant  
6 at the 99% confidence level. The correlations of  $I_{LAPs}$  with BC dry and wet deposition  
7 in WNEC is relatively lower than those in CNCE and ENEC, which is partly due to the  
8 effect of dust in this region (Wang et al., 2013; Zhao et al, 2014). Furthermore, using  
9 the method of multiple linear regression, we fitted  $I_{LAPs}$  using BC dry and wet  
10 deposition and snowfall data. Figure 9d shows the scatterplots of  $I_{LAPs}$  and fitted  $I_{LAPs}$ .  
11 We can find that BC dry and wet deposition and snowfall could totally explain 81% of  
12 the spatial variance of  $I_{LAPs}$ . The result confirms the reasonability of the spatial patterns  
13 of retrieved  $I_{LAPs}$  and thus  $RF_{MODIS}^{LAPs}$  in NEC.

#### 14 4.4. Comparisons of MODIS-Retrieved and In situ Estimated Radiative Forcing by 15 LAPs in Snow

16 Figure 10 shows the distribution of the sample sites and the measured  $BC_{equiv}$   
17 concentration in surface snow at each site. Circles and squares represent the snow  
18 samples collected in 2010 (Wang et al., 2013) and 2014 (Wang et al., 2017),  
19 respectively. Generally,  $BC_{equiv}$  concentration ranges mostly from  $\sim 0.1$  to  $\sim 3.0 \mu\text{g g}^{-1}$   
20 and shows an increase from northwest to southeastern. The highest  $BC_{equiv}$   
21 concentration are found in CNEC while lowest in WNEC. Figure 11a displays a  
22 comparison of MODIS retrieved radiative forcing ( $RF_{MODIS}^{LAPs}$ ) and in situ radiative forcing

1  $(R_{\text{in situ}}^{\text{estimated}})$  estimated based on measured  $BC_{\text{equiv}}$  concentration. In general, the mean  
2 absolute error (MAE) for  $RF_{\text{MODIS}}^{\text{LAPs}}$  against  $R_{\text{in situ}}^{\text{estimated}}$  is  $15.3 \text{ W m}^{-2}$ . The ratios of  
3  $RF_{\text{MODIS}}^{\text{LAPs}}$  to  $R_{\text{in situ}}^{\text{estimated}}$  ( $R_{\text{in situ}}^{\text{MODIS}}$ ) fall mainly in the range of 1-2. The errors indicate larger  
4 positive at lower  $R_{\text{in situ}}^{\text{estimated}}$  values, whereas smaller biases are noted at higher  $R_{\text{in situ}}^{\text{estimated}}$   
5 values. The results of this bias analysis are comparable with those reported by Painter  
6 et al. (2012a). Figure 11b shows a scatterplot of  $R_{\text{in situ}}^{\text{MODIS}}$  versus  $BC_{\text{equiv}}$ . We can find  
7 that  $R_{\text{in situ}}^{\text{MODIS}}$  and  $BC_{\text{equiv}}$  display a good correlation; the best-fitting equation is  
8  $R_{\text{in situ}}^{\text{MODIS}} = 1.690 * BC_{\text{equiv}}^{-0.522}$ , and the  $R^2$  is 0.89 (99% confidence level). This result  
9 indicates that the biases in the  $RF_{\text{MODIS}}^{\text{LAPs}}$  retrievals are negatively correlated with the  
10 LAP concentrations in NEC. Considering that the typical concentration of  $BC_{\text{equiv}}$  in  
11 clean snow in NEC is  $0.15 \mu\text{g g}^{-1}$ , the bias in  $RF_{\text{MODIS}}^{\text{LAPs}}$  can be as high as 350% in some  
12 areas, such as WNEC. In other areas with very polluted snow, such as southern CNEC  
13 (where the  $BC_{\text{equiv}}$  values are typically  $2.5 \mu\text{g g}^{-1}$ ), the bias is ~5%. Thus, considering  
14 the values reported by Wang et al. (2013, 2017), the biases in  $RF_{\text{MODIS}}^{\text{LAPs}}$  largely fall in  
15 the range of ~5% to ~350% in NEC. Comparing Figure 11 with Figure 6, we find that  
16 the biases in the  $RF_{\text{MODIS}}^{\text{LAPs}}$  in polluted snow are comparable with the uncertainties of  
17  $RF_{\text{MODIS}}^{\text{LAPs}}$  due to atmospheric corrections. However, in clean snow, the uncertainties  
18 from atmospheric corrections could not sufficiently explain the biases in retrieved  
19  $RF_{\text{MODIS}}^{\text{LAPs}}$ . There are three probable reasons: (a) for clean snow, retrieved radiative  
20 forcing is very sensitive to MODIS derived surface snow reflectance (Equation 4),  
21 although we have corrected the errors of snow reflectance from the protrusion of  
22 vegetation in our study areas of high snow cover fractions, the uncertainties from

1 fractional snow cover (FSC) calculation and the vegetation reflectance will effectively  
2 influence the corrections of snow reflectance (Equation 5); (b) Painter et al. (2012b)  
3 validated the retrieved radiative forcing by LAPs in snow in the Upper Colorado River  
4 Basin using in situ estimates based on radiation towers, and also found that the biases  
5 in the case of low radiative forcing could be up to several folds. They pointed out that  
6 MODIS can not proceed a continuous spectral measurement of a continuously variable  
7 forcing like that which LAPs afford to snow albedo due to the variably spaced and  
8 discrete bands of MODIS, which prevents a more quantitative retrieval and thus results  
9 into a non-negligible uncertainty in radiative forcing retrieval; (c) We use the average  
10 of MODIS retrieved radiative forcing in a pixel size of  $0.05^\circ \times 0.05^\circ$  to compare with  
11 the in situ radiative forcing calculated using observed  $BC_{equiv}$  concentration with the  
12 sample site located in the center of the pixel. Such a comparison may not be true in  
13 some sites due to the inhomogeneous spatial distribution of snow and LAP contents,  
14 which will influence radiative forcing estimates, especially in clean snow (Zhao et al.  
15 2014). Therefore, we note that the number of sample sites is still limited and more field  
16 campaigns are needed to validate the accuracy of MODIS retrievals and then correct  
17 the retrieved radiative forcing.

#### 18 4.5. Limitations

19 The determination of snow-covered areas represents a limitation of the method used in  
20 this study, which restricts our study to areas with high snow cover fractions; thus, we  
21 cannot estimate  $RF_{MODIS}^{LAPs}$  across the NEC as a whole. In the future, we will attempt to  
22 use the spectral differences between different land cover types to distinguish the

1 spectral reflectance of snow in mixed pixels. This improvement will permit us to  
2 expand our work to areas with limited snow cover. Another limitation is that we retrieve  
3 only the instantaneous radiative forcing at the surface under clear-sky conditions at the  
4 time of MODIS overpass, and these measurements do not represent a time-integrated  
5 average over the studied period. However, the estimation of temporally resolved  
6 radiative forcing is much more difficult, given the significant effects of clouds,  
7 atmospheric components,  $\theta$ , and the time-varying snow reflectance.

## 8 5. Discussions

9 In our study, we didn't retrieve the radiative forcing in the northern and southeastern  
10 parts of NEC. In those regions, snowfall is frequent, the percent of snow cover is very  
11 high and snow is also very deep. For example, in the northern NEC, the averaged snow  
12 depth is  $\sim 20$  cm, and in the areas near Changbai Mountain of the southeastern NEC,  
13 snow depth could be up to  $\sim 40$  cm (Wang et al., 2013). However, due to the presence  
14 of forest cover, the reflected radiation received by sensor aboard the satellite in those  
15 areas is mostly due to trees. For example, Figure 12 shows the true color map of MODIS  
16 in NEC at 23 January 2010, we can see that in the northern and southeastern parts of  
17 NEC, the observed objects from MODIS are almost trees, not the snowpack under trees,  
18 although snow is almost completely covered (Wang et al., 2013). Therefore, in those  
19 forest areas, discussing the radiative forcing by LAPs in snow is extremely difficult due  
20 to the influence of trees. Bond et al. (2006) also indicated that LAPs in snow masked  
21 by forests contribute little to radiative forcing. They further pointed out that model  
22 representation of and forcing sensitivity to cover ranges of forests have not been

1 verified, and this is a boundless uncertainty in modeling radiative forcing by LAPs in  
2 snow at present. However, most modeling studies which simulated the radiative forcing  
3 by LAPs in snow didn't take trees into considerations and estimated the radiative  
4 forcing over the whole boreal forest areas in the Northern Hemisphere. For example,  
5 Flanner et al. (2007) applied SNICAR model coupled a general circulation model to  
6 estimate the radiative forcing and response from BC in snow covered areas over the  
7 whole Northern Hemisphere. Nevertheless, due to the presence of trees in the extensive  
8 boreal forest areas, the simulated radiative forcing is unreal as the incident radiation is  
9 reflected by trees but not by the snowpack. Zhao et al. (2014) simulated BC and dust  
10 and their radiative forcing in seasonal snow in North China. They found that the  
11 radiative forcing by BC and dust is very high in the southeastern NEC, where are forest  
12 areas. But in fact, in those areas the simulated radiative forcing by LAPs is also unreal.  
13 Therefore, we note that estimating the radiative forcing by LAPs in forest areas should  
14 consider into the influence of trees.

## 15 6. Conclusions

16 In this study, we retrieve  $I_{LAPs}$ ,  $R_{eff}$ , and  $RF_{MODIS}^{LAPs}$  across NEC in January-February  
17 from 2003 to 2017 using MODIS data, together with a snow albedo model (SNICAR)  
18 and a radiative transfer model (SBDART). On average,  $I_{LAP}$  is  $\sim 0.27 \pm 0.045$ ,  $R_{eff}$  is  
19  $\sim 261 \pm 32 \mu m$ , and  $RF_{MODIS}^{LAPs}$  is  $\sim 45.1 \pm 6.8 \text{ W m}^{-2}$  in NEC. The distribution of  $RF_{MODIS}^{LAPs}$   
20 presents distinct spatial differences; the lowest value is  $22.3 \text{ W m}^{-2}$ , which occurs in  
21 remote western NEC, and the highest value is  $64.6 \text{ W m}^{-2}$ , which occurs near the  
22 industrial areas in central NEC. Both  $I_{LAPs}$  and  $RF_{MODIS}^{LAPs}$  show larger uncertainties

1 from atmospheric correction as their values are smaller. We make a first attempt to  
2 attribute the variations of radiative forcing based on remote sensing. The results point  
3 out that  $I_{LAPs}$ ,  $R_{eff}$  and  $\theta$  make fractional contributions of 74.6%, 21.2% and 4.2% to  
4 the spatial variance of  $RF_{MODIS}^{LAPs}$  in our study areas across NEC. The result confirms that  
5 the LAP content in snow plays a dominant role in determining the spatial distribution  
6 of  $RF_{MODIS}^{LAPs}$ . We also analyze the distribution of BC dry and wet deposition and snowfall,  
7 find that they could totally explained 81% of the spatial variance of  $I_{LAPs}$ , which  
8 indicates the reasonability of the spatial patterns of  $I_{LAPs}$  and thus  $RF_{MODIS}^{LAPs}$  in NEC.  
9 Finally, we validate the retrieved  $RF_{MODIS}^{LAPs}$  values using in situ estimated radiative  
10 forcing ( $RF_{in\ situ}^{estimated}$ ). The mean absolute error (MAE) of  $RF_{MODIS}^{LAPs}$  against  $RF_{in\ situ}^{estimated}$  is  
11  $15.3\ W\ m^{-2}$ . The biases in the  $RF_{MODIS}^{LAPs}$  retrievals display a negative correlation with  
12 the LAP concentrations in NEC. Considering typical concentrations of  $BC_{equiv}$ , which  
13 range from  $\sim 0.15\ \mu g\ g^{-1}$  to  $\sim 2.5\ \mu g\ g^{-1}$ , the biases in  $RF_{MODIS}^{LAPs}$  fall primarily within the  
14 range of  $\sim 5\%$  to  $\sim 350\%$  in NEC.

1  
 2 **Figure 1.** (a) The spectral albedo of snow with different  $R_{\text{eff}}$  values and BC contents  
 3 simulated using SNICAR. The column bars represent MODIS bands, and the gray areas  
 4 represent the typical solar irradiance in winter in NEC. (b) The reduction in the 300-  
 5 1240 nm spectral-weighted integrated snow albedo as a function of BC for different  
 6  $R_{\text{eff}}$  values and solar zenith angles ( $\theta$ ) simulated using SNICAR. (c) The variations in  
 7 the impurity index ( $I_{\text{LAPs}}$ ) with BC content simulated using SNICAR.

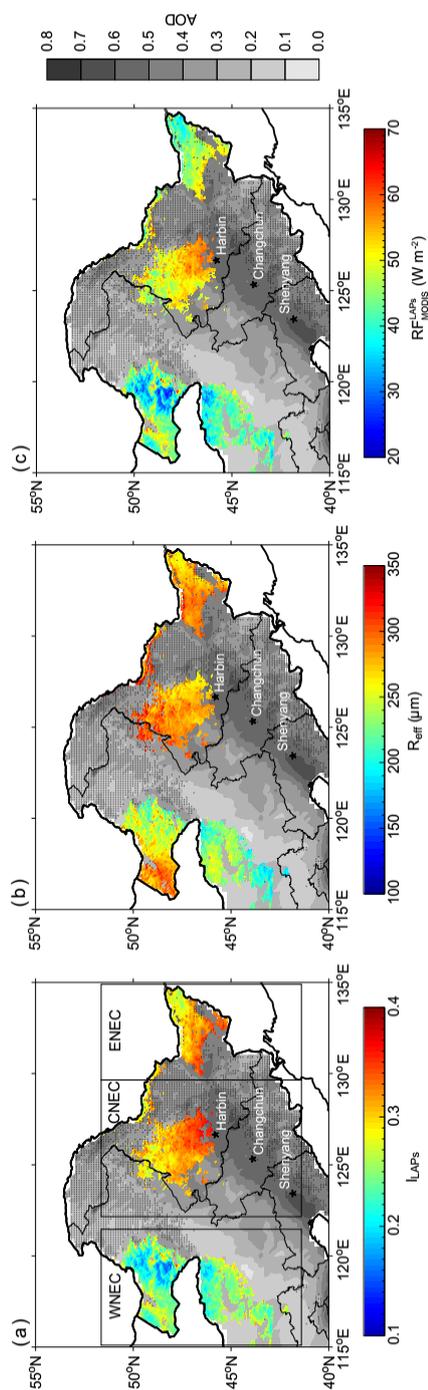

1

2 **Figure 2.** Spatial distribution of (a) MODIS AOD at 550 nm and (b) BC emission  
 3 density density in January-February in NEC. AOD data is from 2003 to 2017 and BC  
 4 emission density is from 2014. The major cities in NEC are also shown in this figure.

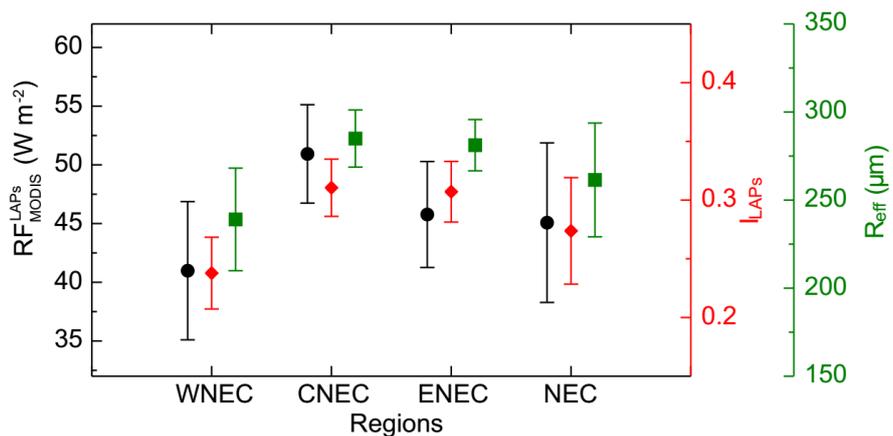

1

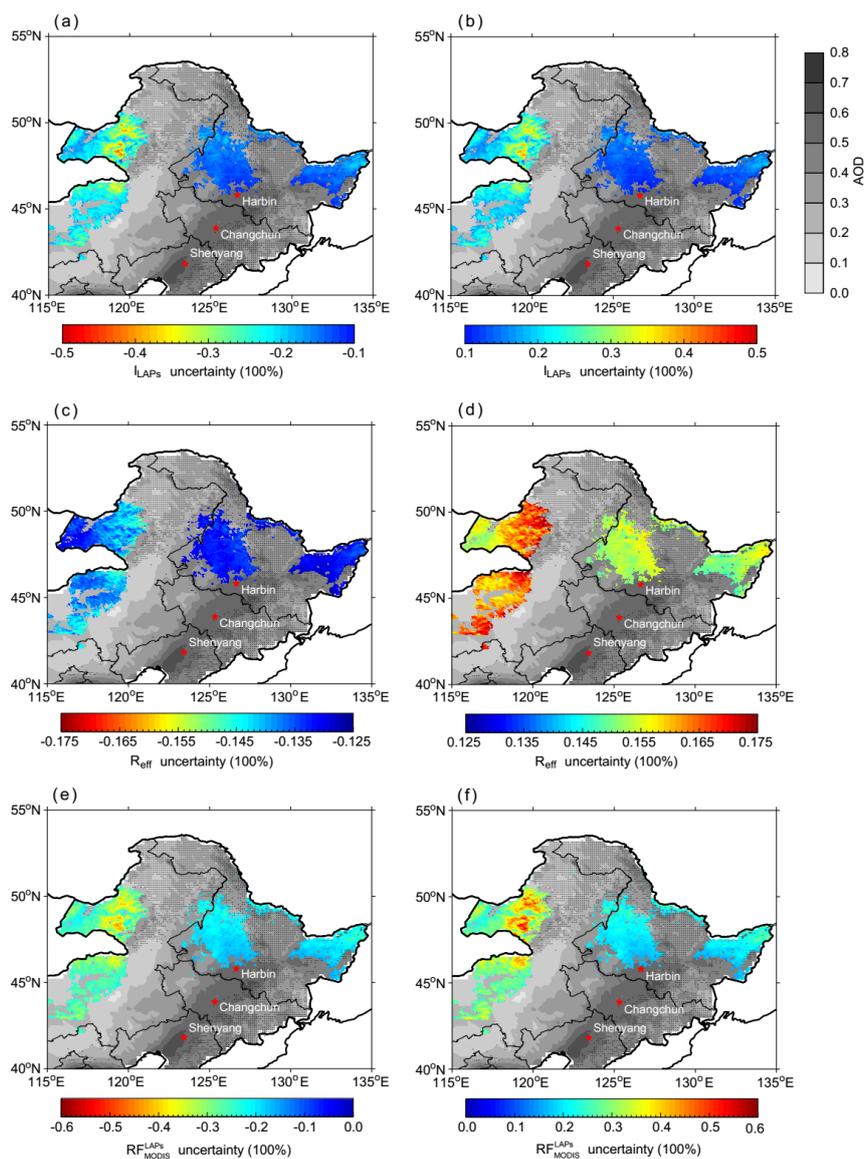

2 **Figure 3.** Spatial distribution of (a) the normalized snowfall frequency in January-  
 3 February from 2003 to 2017 and (b) the different land cover types based on MODIS  
 4 data in NEC.

1  
 2 **Figure 4.** The spatial distributions of average (a)  $I_{LAPs}$ , (b)  $R_{eff}$ , and (c)  $R_{FLAPs\_MODIS}$  in NEC in January-February from 2003-2017. The background  
 3 shows the spatial distribution of MODIS AOD values. The dotted areas are covered by forests. The major cities in NEC are also shown in this  
 4 figure. According to the geographical distribution, we separate the study area into three regions, western NEC (WNEC), central NEC (CNEC) and  
 5 eastern NEC (ENEK).

1  
2 **Figure 5.** Statistics of average  $RF_{MODIS}^{LAPs}$ ,  $I_{LAPs}$ , and  $R_{eff}$  in NEC in January-February  
3 from 2003 to 2017.

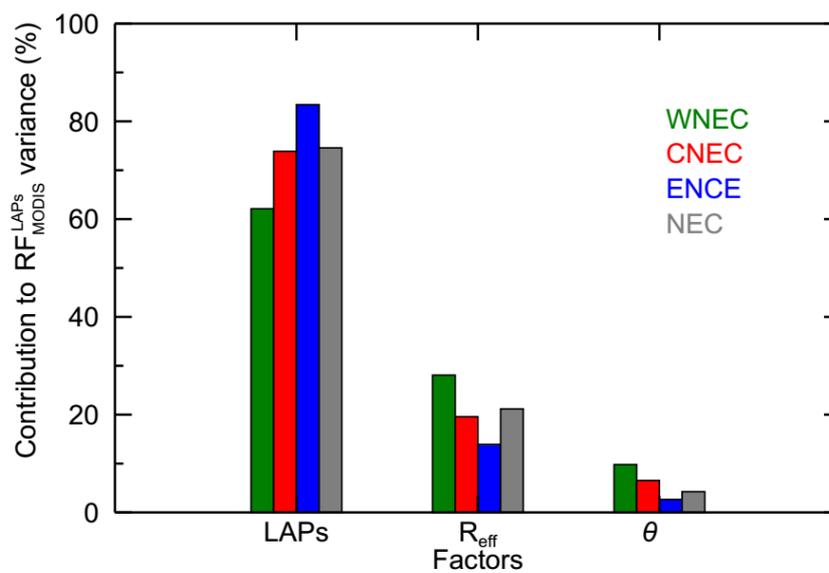

1

2 **Figure 6.** (a) Negative and (b) positive uncertainty of average  $I_{LAPs}$  in NEC in  
3 January-February from 2003 to 2017. (c) and (d) are similar to (a) and (b), but for  $R_{eff}$ .  
4 (e) and (f) are similar to (a) and (b), but for  $RF_{MODIS}^{LAPs}$ . The background shows the spatial  
5 distribution of MODIS AOD values. The dotted areas are covered by forests. The major  
6 cities in NEC are also shown in this figure.

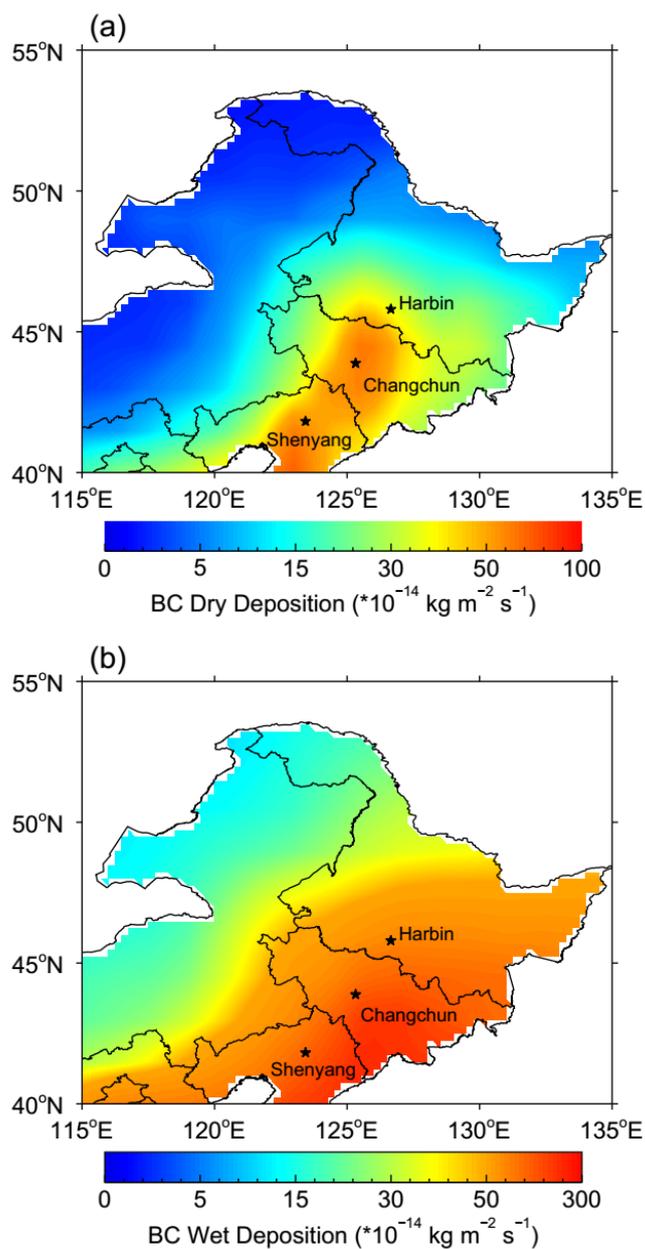

7

8

9

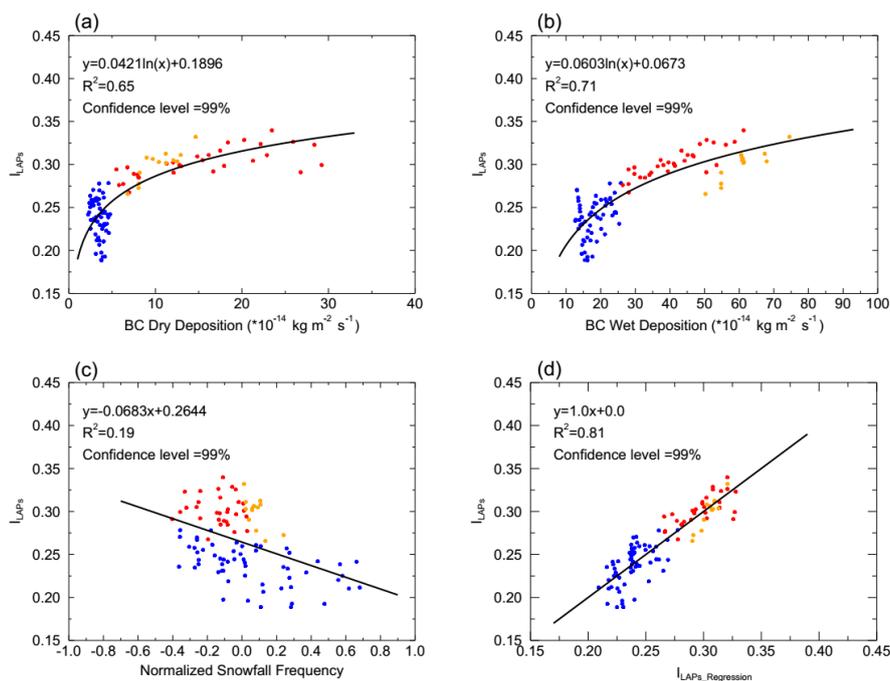

1  
2 **Figure 7.** Fractional contribution of average  $I_{LAPs}$ ,  $R_{eff}$ , and solar zenith angle ( $\theta$ ) to  
3 the spatial variance of  $RF_{MODIS}^{LAPs}$  in January-February from 2003-2017.

1

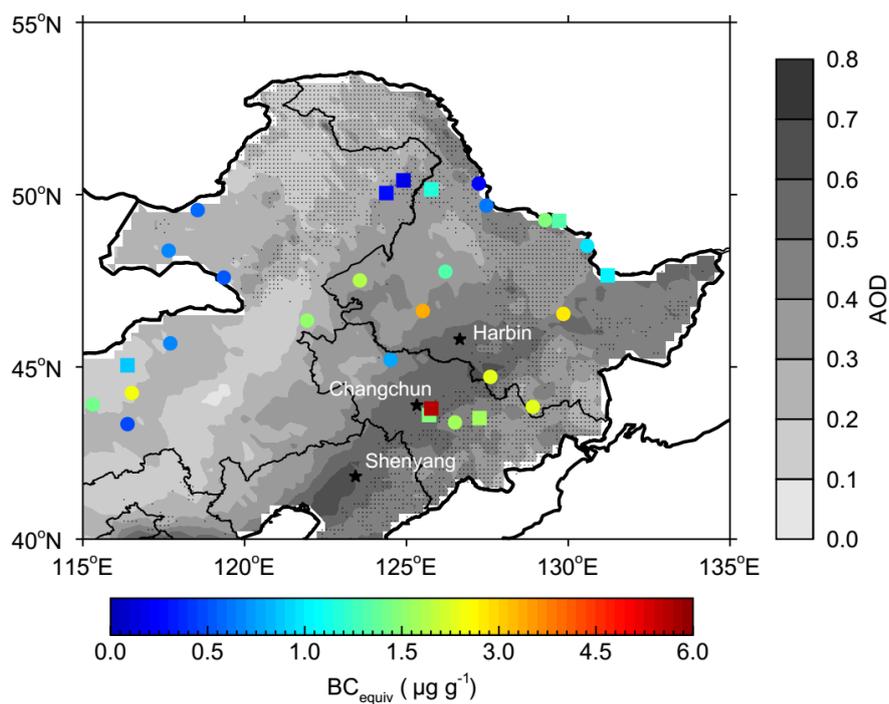

2 **Figure 8.** Spatial distribution of average (a) dry and (b) wet deposition of BC in NEC  
3 in January-February from 2003 to 2005. BC deposition data is only updated to 2005.

4 The major cities in NEC are also shown in this figure.

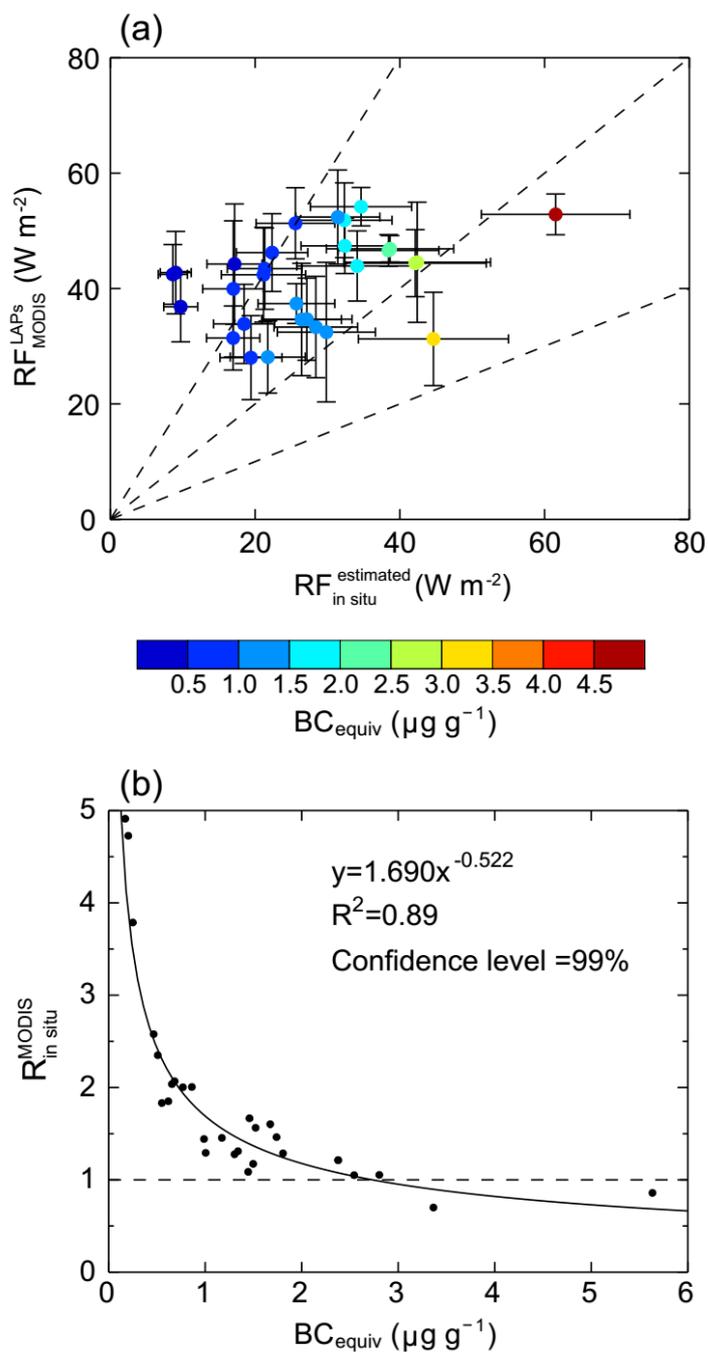

1

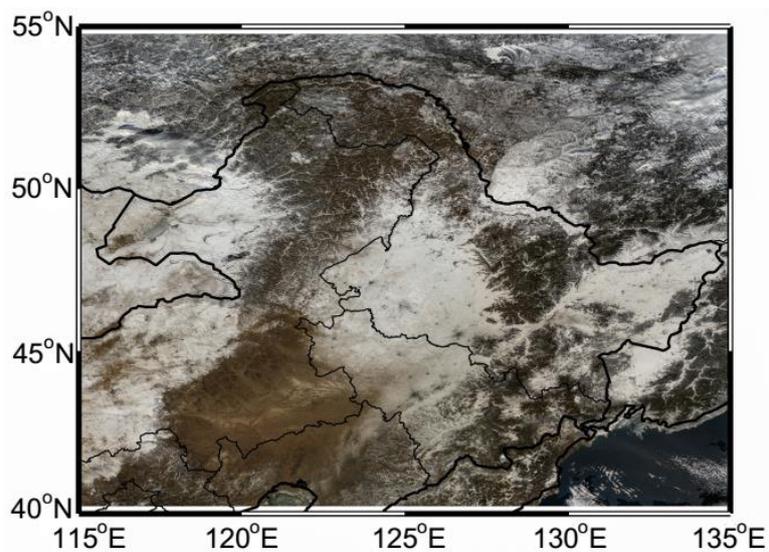

2 **Figure 9.** Scatterplots of (a)  $I_{LAPs}$  versus BC dry deposition, (b)  $I_{LAPs}$  versus BC wet  
3 deposition, (c)  $I_{LAPs}$  versus normalized snowfall frequency, and (d)  $I_{LAPs}$  versus  
4 regressed  $I_{LAPs}$  ( $I_{LAPs\_Regression}$ ), which is regressed with BC dry and wet deposition  
5 and snowfall frequency using multiple linear regression. We note that all data in this  
6 figure is from January-February of 2003-2005 due to that BC deposition data is only  
7 updated to 2005.

1  
2 **Figure 10.** Spatial distribution of the measured  $BC_{equiv}$  concentration in surface snow  
3 in NEC. Circles and squares represent the snow samples collected in 2010 (Wang et al.,  
4 2013) and 2014 (Wang et al., 2017), respectively.

1  
 2 **Figure 11.** Scatterplots of (a) RF<sub>MODIS</sub><sup>LAPs</sup> versus RF<sub>in situ</sub><sup>estimated</sup> and (b) R<sub>in situ</sub><sup>MODIS</sup> versus  
 3 BC<sub>equiv</sub>.
