19 **Abstract:**

20 Brown carbon (BrC) is a special type of organic aerosols (OA), capable of absorbing solar  
21 radiation from near-ultraviolet (UV) to visible wavelengths, which may lead to an increased  
22 aerosol radiative effect in the atmosphere. While high concentrations of OAs have been  
23 observed in the Pearl River Delta (PRD) region of China, the optical properties and  
24 corresponding radiative forcing of BrC in the PRD are still not well understood. In this work,  
25 we conducted a set of comprehensive measurements of atmospheric particulate matter from 29  
26 November 2014 to 2 January 2015 to investigate aerosol compositions, optical properties,  
27 source origins and radiative forcing effects at a suburban station in Guangzhou. The particle  
28 absorption Ångström exponent (AAE) was deduced and utilized to differentiate light absorption  
29 by BrC from that by black carbon (BC). The results showed that the average absorption  
30 contributions of BrC were  $34.1 \pm 8.0\%$  at 370 nm,  $23.7 \pm 7.3\%$  at 470 nm,  $16.0 \pm 6.7\%$  at 520 nm,  
31  $13.0 \pm 5.4\%$  at 590 nm and  $8.7 \pm 4.3\%$  at 660 nm. A sensitivity analysis of the evaluation of the  
32 absorption Ångström exponent of BC ( $AAE_{BC}$ ) was conducted based on the Mie theory  
33 calculation assuming that the BC-containing aerosol was mixed with the core-shell and external  
34 configurations. The corresponding uncertainty in  $AAE_{BC}$  was acquired. We found that  
35 variations in the imaginary refractive index (RI) of the BC core can significantly affect the  
36 estimation of  $AAE_{BC}$ . However,  $AAE_{BC}$  was relatively less sensitive to the real part of the RI  
37 of the BC core and was least sensitive to the real part of the RI of the nonlight absorbing shell.  
38 BrC absorption was closely related to aerosol potassium cation content ( $K^+$ ), a common tracer  
39 of biomass burning emissions, which was most likely associated with straw burning in the rural  
40 area of the western PRD. Diurnal variation in BrC absorption revealed that primary organic  
41 aerosols had a larger BrC absorption capacity than secondary organic aerosols (SOAs).  
42 Radiative transfer simulations showed that BrC absorption may cause  $2.3 \pm 1.8 \text{ W m}^{-2}$  radiative  
43 forcing at the top of the atmosphere (TOA) and contribute to  $15.8 \pm 4.4\%$  of the aerosol warming  
44 effect. A chart was constructed to conveniently assess the BrC radiative forcing efficiency in  
45 the studied area with reference to certain aerosol single-scattering albedo ( $SSA$ ) and BrC  
46 absorption contributions at various wavelengths. Evidently, the BrC radiative forcing efficiency  
47 was higher at shorter wavelengths.

**Keywords:** Brown carbon, Black carbon, Absorption Ångström exponent, Radiative forcing, Pearl River Delta.

## 48 **1 Introduction**

49 Black carbon (BC) and organic carbon (OC) are dominant carbonaceous aerosol components  
50 that mainly originate from biomass burning in a global scale (Bond et al., 2004) and have  
51 attracted great environmental concerns in rapidly developing regions. Carbonaceous aerosols  
52 can not only exert adverse impacts on public health, similar to other particulate matters, but  
53 also significantly affect the terrestrial radiation balance with enormous uncertainties. In  
54 previous studies, BC was often considered to be the only light-absorbing species (Andreae and  
55 Gelencser, 2006), and OC was believed to only be able to scatter light, i.e., causing a cooling  
56 effect (Bond et al., 2011). Nevertheless, it has been reported that some fraction of organic  
57 aerosols (OAs) may also specifically contribute to light absorption from the near-ultraviolet  
58 (UV) to visible wavelength range, which is referred to as brown carbon (BrC) (Kirchstetter et  
59 al., 2004). BrC optical properties are strongly affected by its chemical composition and physical  
60 structure, which are related to different BrC sources. BrC can originate not only from direct  
61 emissions, including smoldering, biomass burning or any type of incomplete fuel combustion  
62 process (T. C. Bond et al., 1999; Cheng et al., 2011), but also from secondary organic aerosol  
63 formation processes, such as aqueous phase reactions in acidic solutions (Desyaterik et al., 2013)  
64 or volatile organic compound (VOC) oxidation (Laskin et al., 2015; Sareen et al., 2010). In  
65 addition, BrC could have a complicated molecular composition and intermix with other  
66 substances, such as BC, non-absorbing OAs and other inorganic materials, making it  
67 complicated to investigate BrC optical properties.

68 BC absorption is commonly assumed to be covering the full wavelength-range. However, the  
69 light absorption property of BrC is believed to be more wavelength-dependent, which can be  
70 represented by distinct absorption Ångström exponent (AAE) values, i.e., the power exponent  
71 of the light absorption coefficient. A typical threshold for the AAE of BC ( $AAE_{BC}$ ) of 1.6 has  
72 been recommended to distinguish BrC from BC (Lack and Cappa, 2010), and the AAE of BrC  
73 has been reported as having a wider range (2 to 7) (Hoffer et al., 2005). Based on the difference  
74 in the wavelength dependence of light absorption between BC and BrC, previous studies have

75 applied the AAE method to differentiate light absorption by BrC through multiwavelength  
76 optical measuring apparatus, such as 3-wavelength Photoacoustic Soot Spectrometer (PASS-3)  
77 (Lack and Langridge, 2013), multiwavelength Aethalometer (Olson et al., 2015), etc. Based on  
78 the AAE method, the BrC absorption contribution has been estimated to be approximately 6 to  
79 41% of total aerosol light absorption at short wavelengths, e.g., at 370 nm and 405 nm  
80 (Washenfelder et al., 2015). A uniform  $AAE_{BC}$  from  $\sim 300$  nm up to  $\sim 700$  nm (Moosmüller et  
81 al., 2011) is commonly used when evaluating the BrC absorption contribution using the AAE  
82 method. However, it has been reported that the  $AAE_{BC}$  can be influenced by the mixing state,  
83 BC core size and morphology (Lack and Cappa, 2010). The lensing effect of the coating shell  
84 may enhance BC light absorption, the magnitude of which may also depend on wavelength and  
85 can alter the value of  $AAE_{BC}$  (Liu et al., 2018). Moreover, different values of  $AAE_{BC}$  have been  
86 found in the near-infrared and UV ranges (Wang et al., 2018). Therefore, using the default value  
87 of  $AAE_{BC} = 1$  may lead to uncertainty in BrC absorption coefficient estimation.

88 Quantifying BrC optical absorption accurately is essential to interpret aerosol optical depth  
89 (AOD), and the corresponding aerosol direct radiative forcing (DRF) on the atmosphere can  
90 also be evaluated if the single-scattering albedo (*SSA*) and extinction coefficient of aerosols are  
91 known. The estimation of the DRF of BrC has shown a distinct seasonal variation, indicating  
92 the influence of different absorption properties of BrC (Arola et al., 2015). A global simulation  
93 study indicated that the average warming effect at the TOA caused by BrC absorption can be  
94 up to  $0.11 \text{ W m}^{-2}$ , corresponding to  $\sim 25\%$  of that predicted from BC absorption only (Feng et  
95 al., 2013).

96 During the last three decades, rapid economic development has led to severe air pollution  
97 problems in the PRD region (Chan and Yao, 2008). With rapid increases in the automobile  
98 population and factories, high loadings of SOAs have often been observed (Tan et al., 2016b).  
99 Biofuel usage may also play a significant role during wintertime air pollution events in the PRD,  
100 indicating that the contribution from BrC light absorption cannot be ignored (Wu et al., 2018).  
101 Recently, BrC light absorption has been quantified by Qin et al. (2018) using the AAE method  
102 in the PRD region. OA chemical composition was simultaneously measured by a high-  
103 resolution time-of-flight aerosol mass spectrometer, and it was found that organic aerosols  
104 originating from biomass burning possessed the most intense absorption capability and were

105 largely responsible for BrC absorption. Qin et al. (2018) also suggested that correlations  
106 between OA chemical compositions and BrC absorption were wavelength-dependent.  
107 In this paper, we applied the homologous AAE differentiation method to quantify the fraction  
108 of aerosol light absorption by BrC using the measurements from a seven-wavelength  
109 Aethalometer. The potential error incurred with this methodology was determined using Mie  
110 theory simulations, especially for various complex refractive indexes of the BC core and the  
111 coating material. The correlation between BrC light absorption and water-soluble ions, which  
112 is used as the source tracer, was employed to identify potential BrC sources. An atmospheric  
113 radiative transfer model has also been applied to evaluate the impact of BrC on direct radiative  
114 forcing using surface-based aerosol optical properties and satellite-based surface-albedo data.  
115 The magnitudes of aerosol radiative forcing at the top of the atmosphere due to BC and BrC  
116 were also individually quantified.

## 117 **2 Methodology**

### 118 **2.1 Sampling site**

119 Field observations were conducted at the Panyu station (113°21'E, 23°00'N), which is a  
120 monitoring site of the Chinese Meteorological Administration (CMA) Atmospheric Watch  
121 Network (CAWNET) that is located on the summit of Dazhengang Mountain (approximately  
122 150 m above sea level) in Guangzhou, China. Figure 1 shows the location of the Panyu site,  
123 which is situated at the center of the PRD and is separated from residential areas by at least 500  
124 m. Some agricultural fields can be found to the west of the site. Although there were no  
125 significant pollution sources nearby, this suburban site was strongly affected by pollutants  
126 transported from the urban area of Guangzhou and crop residual fires transported from the rural  
127 area of the PRD. The field campaign was conducted from 29 November 2014 to 2 January 2015.  
128 During the measurement period, aerosol light scattering and extinction, BC concentration,  
129 particle number size distribution (PNSD), OC concentration, and the water-soluble ion  
130 concentrations of PM<sub>2.5</sub> were continuously monitored.

### 131 **2.2 Measurements and data analysis**

132 All instruments were housed inside the 2<sup>nd</sup> floor measurement room of a ~5-m tall, 2-story  
133 building. The ambient sample was taken on the roof by a 2-m long, 12.7-mm OD stainless steel  
134 inlet, and a PM<sub>2.5</sub> cyclone sampler was also used. The metal tubing was thermally insulated and

135 maintained at a constant temperature of  $\sim 25^{\circ}\text{C}$ . A diffusion drier was also used in-line to dry  
136 the relative humidity (RH) of the air sample below 30% before further analysis.

### 137 **2.2.1 Measurements of relevant species**

138 A TSI-3936 scanning mobility particle sizer (SMPS) and a TSI-3321 aerodynamic particle sizer  
139 (APS) were utilized to measure the 10 to 500 nm mobility diameter and 0.5 to 2.5  $\mu\text{m}$   
140 aerodynamic diameter of the PNSD, respectively. The aerodynamic diameters of the APS data  
141 were converted into mobility diameters using a material density of  $1.7\text{ g cm}^{-3}$ . A detailed data  
142 merging method has been described by Cheng et al. (2006). Furthermore, the pipe diffusion  
143 loss of SMPS has been corrected using the empirical formula proposed by Kulkarni et al. (1996).  
144 An AE-33 Aethalometer (Magee Scientific Inc.) was utilized for BC mass concentration  
145 measurement, which was derived from optical attenuation using a mass absorption cross section  
146 (MAC) of  $7.77\text{ m}^2\text{ g}^{-1}$  at 880 nm. The sensitivity of AE-33 was approximately  $0.03\text{ }\mu\text{g m}^{-3}$  for  
147 a 1-min time resolution and a 5.0 liter per minute (LPM) sample flow rate.

148 The  $\text{PM}_{2.5}$  mass concentration was measured by an Environment Dust Monitor (Model  
149 EDM180, GRIMM Inc.), which monitored the mass concentration of  $\text{PM}_{2.5}$  and  $\text{PM}_{10}$   
150 simultaneously.

151 Water-soluble ions (potassium ( $\text{K}^+$ ), calcium ( $\text{Ca}^{2+}$ ), magnesium ( $\text{Mg}^{2+}$ ), chloride ( $\text{Cl}^-$ ), sulfate  
152 ( $\text{SO}_4^{2-}$ ), nitrate ( $\text{NO}_3^-$ ), and ammonium ( $\text{NH}_4^+$ ) were measured with the Monitor for AeRosols  
153 and Gases in Air (MARGA) (Model ADI2080, Metrohm Inc.), which is an online analyzer for  
154 semi-continuous measurements of gases and water-soluble ions in aerosols (Li et al., 2010).  
155 The MARGA was automatically calibrated with standard internal solutions during field  
156 measurement. The MARGA utilized its own  $\text{PM}_{2.5}$  sampling system provided by the  
157 manufacturer.

158 The OC mass concentration was measured by a Sunset online OC/EC analyzer (Model RT-4)  
159 with a laser transmittance-based charring correction (Wu et al., 2018). The sample flow rate of  
160 the OC/EC analyzer was maintained at 8 LPM. For each measurement cycle (one hour),  
161 samples were collected onto a quartz filter within the first 45 min and then thermal-optically  
162 analyzed during the remaining 15 min. First, OC was completely volatilized in oxygen-free  
163 helium with a stepwise ramped temperature ( $600^{\circ}\text{C}$  and  $840^{\circ}\text{C}$ ). In the second stage, the  
164 temperature was reduced to  $550^{\circ}\text{C}$ , and then EC and pyrolyzed carbon (PC) were combusted

165 in an oxidizing atmosphere (10% oxygen in helium), while the temperature was increased up  
 166 to 870 °C step by step. The CO<sub>2</sub> converted from all of the carbon components was then  
 167 quantified by a nondispersive infrared absorption CO<sub>2</sub> sensor (Lin et al., 2009). An internal  
 168 calibration peak made by 5% methane in helium was applied to quantify OC and EC. To correct  
 169 the PC converted from OC to EC, a tunable pulsed diode laser beam was used to monitor the  
 170 laser transmittance through the quartz filter throughout the thermal-optical analysis (Bauer et  
 171 al., 2012).

### 172 **2.2.2 Measurements of optical properties**

173 Light extinction by aerosols at 532 nm was detected using a cavity ring-down aerosol extinction  
 174 spectrometer (CRDS) (Model XG-1000, Hexin Inc.) by measuring the decay times of laser  
 175 intensity through the aerosol-containing sample and the filtered background air sample under  
 176 the same conditions. The extinction coefficient ( $\sigma_{ext}$ ) was calculated using the procedure  
 177 described by Khalizov et al. (2009).

178 Aerosol total scattering ( $\sigma_{sp}$ ) was measured by a TSI-3563 integrated nephelometer at three  
 179 wavelengths (i.e., 450 nm, 550 nm, and 700 nm) and was calibrated with CO<sub>2</sub> following the  
 180 manual instructions. Particle free air was used to check the nephelometer background signal  
 181 once every two hours. The scattering coefficients at other wavelengths were extrapolated using  
 182 the following equations:

$$183 \quad SAE = -\frac{\ln(\sigma_{scat,\lambda_0}) - \ln(\sigma_{scat,550nm})}{\ln(\lambda_0) - \ln(550)} \quad (1)$$

$$184 \quad \sigma_{scat}(\lambda) = \sigma_{scat}(550) \cdot \left(\frac{\lambda}{550}\right)^{-SAE} \quad (2)$$

185 where  $\lambda_0=450$  nm is for wavelengths less than 550 nm and  $\lambda_0=700$  nm is for wavelengths greater  
 186 than 550 nm.

187 The Aethalometer is also used for multi-wavelength light absorption measurements in this study.  
 188 The seven-wavelength aerosol light attenuation coefficients ( $\sigma_{ATN}$ ) were converted into aerosol  
 189 light absorption coefficients ( $\sigma_{abs}$ ) using Eq. (3) (Coen et al., 2010), where  $k$  is the parameter  
 190 that accounts for the loading effect, ATN is the light attenuation through the filter with sample  
 191 loading and  $C_{ref}$  is a fixed multiple scattering parameter.

$$192 \quad \sigma_{abs} = \frac{\sigma_{ATN}}{(1 - k \cdot ATN) \cdot C_{ref}} \quad (3)$$

193 The real-time  $k$  value was retrieved using the dual-spot loading correction algorithm developed

194 by Drinovec et al. (2015). The detailed formula of ATN can also be found in Drinovec et al.  
 195 (2015).  $C_{ref}$  is considered a constant that strongly depends on the filter matrix effect. However,  
 196 some studies have suggested that  $C_{ref}$  may vary with wavelength (Arnott et al., 2005; Segura et al.,  
 197 2014). For internal combustion engines and biomass burning,  $C_{ref}$  at 370 nm was expected to be  
 198 approximately 12% and 18% less than  $C_{ref}$  at 532 nm for the aerosol component, respectively  
 199 (Schmid et al., 2006). Different ambient observations also showed that  $C_{ref}$  may have regional  
 200 specificity, even though it was retrieved by the same methodology (Coen et al., 2010). In this  
 201 study,  $C_{ref}=3.29$  was used in Eq. (3) at each wavelength, and this value was derived from the  
 202 slope of  $\sigma_{ATN}$  measured by the Aethalometer vs.  $\sigma_{abs}$ , which was deduced from the CRDS and  
 203 nephelometer measurements. This  $C_{ref}$  was also very similar to the  $C_{ref}$  of 3.48 determined from  
 204 an inter-comparison study between an Aethalometer and a photoacoustic soot spectrometer  
 205 during a field campaign conducted in the PRD region in 2004 (Wu et al., 2009).

206 The BC light absorption at certain wavelengths was derived from the absorption coefficient  $\sigma_{abs}$   
 207 according to Beer-Lambert's law, and its variation between different pairs of wavelengths (i.e.,  
 208  $\sigma_{abs,BC,\lambda}$ ) is denoted by the absorption Ångström exponent (AAE) equation developed by  
 209 Ångström (1929):

$$210 \quad \sigma_{abs,BC,\lambda} = \sigma_{abs,BC,\lambda_0} \times (\lambda_0 / \lambda)^{-AAE_{BC}} \quad (4)$$

211 It has been suggested that the AAE of BC may vary between short and long wavelength ranges  
 212 (Lack and Cappa, 2010); hence, applying a wavelength-independent  $AAE_{BC}$  may lead to  
 213 uncertainties in the BC absorption calculation from one wavelength to another. In this work,  
 214 the light absorptions of BC at various wavelengths were retrieved by a modified wavelength-  
 215 dependent AAE differentiation method conducted by Wang et al. (2018):

$$216 \quad \sigma_{abs,BC,\lambda_1} = \sigma_{abs,BC,880nm} \times \left(\frac{880}{\lambda_1}\right)^{AAE_{BC,520-880nm}} \quad (5.1)$$

$$217 \quad \sigma_{abs,BC,\lambda_2} = \sigma_{abs,BC,880nm} \times \left(\frac{880}{520}\right)^{AAE_{BC,520-880nm}} \times \left(\frac{520}{\lambda_2}\right)^{AAE_{BC,370-520nm}} \quad (5.2)$$

218 Here,  $\sigma_{abs,BC,\lambda_1}$  represents the absorption coefficient due to only BC greater than 520 nm, and  
 219  $\sigma_{abs,BC,\lambda_2}$  represents the absorption coefficient of BC less than 520 nm.  $AAE_{BC,\lambda_i-\lambda_{i+1}}$  (i=1, 2  
 220 and 3) represents the AAE of BC between a longer and shorter wavelength at  $\lambda_i=880, 520$  and  
 221 370 nm and was calculated as:

222 
$$AAE_{BC,\lambda_i-\lambda_{i+1}} = \frac{\ln(\sigma_{abs,BC,\lambda_i}) - \ln(\sigma_{abs,BC,\lambda_{i+1}})}{\ln(\lambda_i) - \ln(\lambda_{i+1})} \quad (6)$$

223 Accordingly, BrC absorption at a certain wavelength  $\lambda$  ( $\sigma_{abs,BrC,\lambda}$ ) was equal to the value of total  
 224 aerosol absorption ( $\sigma_{abs,\lambda}$ ) minus BC absorption ( $\sigma_{abs,BC,\lambda}$ ):

225 
$$\sigma_{abs,BrC,\lambda} = \sigma_{abs,\lambda} - \sigma_{abs,BC,\lambda} \quad (7)$$

226 The light absorption data at 880 nm ( $\sigma_{abs,880nm}$ ) were selected to represent BC absorption  
 227 ( $\sigma_{abs,BC,880nm}$ ), which shall not be affected by BrC (Drinovec et al., 2015). It has been reported  
 228 that the dust-related contributions of PM<sub>2.5</sub> were normally less than 5% in wintertime in  
 229 Guangzhou; therefore, the influence from dust could be negligible in this study (Huang et al.,  
 230 2014).

### 231 2.2.3 Estimation of AAE<sub>BC</sub>

232 Traditionally, AAE<sub>BC</sub> was believed to be close to 1.0 (Bodhaine, 1995), which has been  
 233 commonly used for BC measurements (Olson et al., 2015). However, studies have  
 234 demonstrated that AAE<sub>BC</sub> can be affected by the refractive index of coating materials, mixing  
 235 state, morphology, and BC core size (Liu et al., 2015). Therefore, using the default AAE<sub>BC</sub> = 1  
 236 may lead to uncertainty in BrC absorption estimation. To obtain the correct AAE<sub>BC</sub>, a series of  
 237 Mie theory calculations were conducted using a simplified core-shell model (Bohren and  
 238 Huffman, 1983; Wang et al., 2018). We used a modified BHCOAT code and BHMIE code to  
 239 calculate the aerosol optical properties of the core-shell and external mixture at different  
 240 wavelengths (Cheng et al., 2006). In the Mie theory, a particle is taken as a perfect  
 241 homogeneous sphere, and its extinction and scattering efficiencies,  $Q_{ext,Mie,\lambda}$  and  $Q_{scat,Mie,\lambda}$ ,  
 242 respectively, are expressed as (Mie, 1908; Seinfeld and Pandis, 1998):

243 
$$Q_{ext,Mie,\lambda} = \frac{2}{\alpha^2} \sum_{n=1}^{\infty} [(2n+1)Re(a_n + b_n)] \quad (8)$$

244 
$$Q_{scat,Mie,\lambda} = \frac{2}{\alpha^2} \sum_{n=1}^{\infty} [(2n+1)(|a_n|^2 + |b_n|^2)] \quad (9)$$

245 where  $\alpha = \pi D_p / \lambda$  is the size parameter;  $a_n$  and  $b_n$  are functions of the complex refractive  
 246 index (RI) and  $\alpha$  in the Riccati-Bessel form, respectively.  $Re$  in Eq. (8) denotes that only the  
 247 real part of RI is taken. The absorption efficiency ( $Q_{abs,Mie,\lambda}$ ) is thus the difference between  
 248 the extinction and scattering efficiencies:

249 
$$Q_{abs,Mie,\lambda} = Q_{ext,Mie,\lambda} - Q_{scat,Mie,\lambda} \quad (10)$$

250 Then, the absorption coefficient  $\sigma_{abs,Mie,\lambda}$  was obtained by the following (Bricaud and Morel,  
251 1986):

252 
$$\sigma_{abs,Mie,\lambda} = \int Q_{abs,Mie,\lambda} \cdot \left(\frac{\pi}{4} D_p^2\right) \cdot N(\log D_p) \cdot d \log D_p \quad (11)$$

253 where  $N(\log D_p)$  is the PNSD function. A two-component parameterization of dry particles,  
254 i.e., the BC core and the nonlight-absorbing species, was applied to calculate aerosol optical  
255 properties here (Wex et al., 2002).  $\tilde{m}_{core}$  represents the RI of the BC core, and  $\tilde{m}_{non}$  represents  
256 the RI of nonlight-absorbing particles.

257 In a realistic atmosphere, some nonlight-absorbing particles may exist independently without  
258 BC (Liu et al., 2013; Cheung et al., 2016). In this work, the portion of nonlight-absorbing  
259 particles at a certain size ( $D_p$ ) was determined by our previous measurements at the same site  
260 using a Volatility Tandem Differential Mobility Analyzer (V-TDMA), during which completely  
261 vaporized (CV) particles at 300°C were referred to as nonlight-absorbing particles that  
262 externally mixed with other BC-containing particles. Thus, the PNSD of CV particles  
263 ( $N(\log D_p)_{CV}$ ) and BC-containing particles ( $N(\log D_p)_{BC}$ ) can be given by the following  
264 equations:

265 
$$N(\log D_p)_{CV} = N(\log D_p)_{measure} \cdot \Phi(D_p)_{N,CV} \quad (12)$$

266 
$$N(\log D_p)_{BC} = N(\log D_p)_{measure} \cdot (1 - \Phi(D_p)_{N,CV}) \quad (13)$$

267 where  $N(\log D_p)_{measure}$  is the PNSD of the measured particles from SMPS and APS.  
268  $\Phi(D_p)_{N,CV}$  was the number fraction of CV particles in different size bin.

269 A previous study applied three kinds of BC mixture models to calculate the aerosol optical  
270 properties, including external, homogenously internal and core-shell mixtures (Bohren and  
271 Huffman, 2007; Seinfeld and Pandis, 1998). To quantify the mixing state of BC,  $r_{ext}$  was defined  
272 as the mass fraction of externally mixed BC ( $M_{ext}$ ) in total BC ( $M_{BC}$ ):

273 
$$r_{ext} = \frac{M_{ext}}{M_{BC}} \quad (14)$$

274 Tan et al. (2016) suggested that two extreme conditions of external and core-shell mixtures  
275 comprised the actual mixing state of BC in the PRD. Hence, we simply divided the PNSD of  
276 BC into the PNSD from an external mixture of BC and a core-shell mixture of BC. The PNSDs

277 of externally mixed BC particles and core-shell mixed BC particles were referred to by the  
 278 following equations with a given  $r_{ext}$ .

$$279 \quad N(\log D_p)_{ext} = N(\log D_p)_{BC} \cdot f_{BC} \cdot r_{ext} \quad (15)$$

$$280 \quad N(\log D_p)_{core-shell} = N(\log D_p)_{BC} \cdot (1 - f_{BC} \cdot r_{ext}) \quad (16)$$

281  $f_{BC}$  was defined as the BC volume fraction in the BC-containing particle volume, which can be  
 282 converted from the BC mass concentration:

$$283 \quad f_{BC} = \frac{M_{BC}}{\rho_{BC} \cdot \sum_{D_p} N(\log D_p)_{BC} \cdot \left(\frac{\pi}{6} \cdot D_p^3\right)} \quad (17)$$

284 where  $\rho_{BC}$  is the density of BC and is assumed to be  $1.5 \text{ g cm}^{-3}$  (Ma et al., 2012);  $M_{BC}$  is the BC  
 285 mass concentration derived from the multi-angle absorption photometer (MAAP), which was  
 286 obtained by an empirical formula from the Aethalometer that measured the BC concentration  
 287 ( $M_{BC,AE}$ ), as proposed by Wu et al. (2009):

$$288 \quad M_{BC} = 0.897 \cdot M_{BC,AE} - 0.062 \quad (18)$$

289 The PNSDs of externally mixed nonlight-absorbing particles and externally mixed BC particles  
 290 were input into the BHMIE code, and the PNSD of the core-shell mixed particles was imported  
 291 into the BHCOAT code. Another critical parameter for the core-shell model was the diameter  
 292 of the BC core. For the simplified core-shell model we applied, the visualization was that a  
 293 homogeneous BC core sphere was encapsulated in a shell of non-absorbing coating (Bohren  
 294 and Huffman, 2007). Without size-resolved coating thickness measurements, core-shell mixed  
 295 particles simply assumed that cores with the same diameter had the same coating thickness.  
 296 Therefore, the diameter of the BC core was calculated as follows:

$$297 \quad D_{core} = D_p \cdot \left( \frac{f_{BC} - f_{BC} \cdot r_{ext}}{1 - f_{BC} \cdot r_{ext}} \right)^{\frac{1}{3}} \quad (19)$$

298  $D_{core}$  and  $D_p$  are inputted as parameters into  $a_n$  and  $b_n$ , respectively, which was described by  
 299 Bohren and Huffman (2007). Thus, the  $\sigma_{abs,BC,Mie, \lambda_i}$  values of all six wavelengths were  
 300 calculated through the Mie model, and then the  $AAE_{BC}$  values of those five wavelengths were  
 301 obtained using Eq. (6). The performance of this empirically determined calculation method has  
 302 been compared with other possible BC mixing schemes in details (see Table 1).

### 303 **2.2.4 Atmospheric radiative transfer model**

304 In this work, the Santa Barbara DISORT Atmospheric Radiative Transfer (SBDART) model  
 305 was employed to estimate the DRF of BrC absorption, i.e., its effects on the downward and

306 upward fluxes ( $F$  in  $\text{W m}^{-2}$ ) of solar radiation at the TOA. SBDART is a software tool that can  
 307 be used to compute plane-parallel radiative transfer under both clear and cloudy conditions  
 308 within the atmosphere. More details about this model have been described by Ricchiazzi et al.  
 309 (1998). Both ground measurements and remote sensing data were used in the simulation. The  
 310 surface albedo was derived from a 500 m resolution MODIS BRDF/albedo model parameter  
 311 product (MCD43A3, daily). The MCD43A3 products are the total shortwave broadband black-  
 312 sky albedo ( $\alpha_{BSA}$ ) and white-sky albedo ( $\alpha_{WSA}$ ), while the actual surface albedo ( $\alpha$ ) was  
 313 computed from a linear combination of  $\alpha_{WSA}$  and  $\alpha_{BSA}$ , which were weighted by the diffuse ratio  
 314 ( $r_d$ ) and direct ratio ( $1-r_d$ ), respectively:

$$315 \quad \alpha = (1 - r_d) \cdot \alpha_{BSA} + r_d \cdot \alpha_{WSA} \quad (20)$$

316  $r_d$  was obtained from an exponential fit of Eq. (21) based on empirical observations (Stokes and  
 317 Schwartz, 1994; Roesch, 2004):

$$318 \quad r_d = 0.122 + 0.85e^{-4.8\mu_0} \quad (21)$$

319 where  $\mu_0$  is the cosine of the zenith angle, which is calculated by the model for any specified  
 320 date, time, and latitude and longitude of the site. The surface-based aerosol optical properties,  
 321 including the aerosol light absorption coefficients of both BC and BrC, i.e., differentiated from  
 322 each other under the assumption of uniform  $\text{AAE}_{\text{BC}}$ , along with the nephelometer-measured  
 323 aerosol scattering coefficients, were used to calculate the  $SSA$  at different wavelengths  
 324 according to Eq. (22),

$$325 \quad SSA(\lambda) = \frac{\sigma_{\text{scat}, \lambda}}{\sigma_{\text{abs}, \text{BrC}, \lambda} + \sigma_{\text{abs}, \text{BC}, \lambda} + \sigma_{\text{scat}, \lambda}} \quad (22)$$

326 which was then used in the model calculation. Finally, the AOD and asymmetry factor (ASY)  
 327 at 440, 675 and 870 nm were derived from the Aerosol Robotic Network (AERONET)  
 328 measurements at the Hong Kong Polytechnic University site (Holben et al., 1998), which is  
 329 approximately 115 km to the southeast of the Panyu site. The tropical atmospheric profile was  
 330 used in the SBDART model based on the prevailing weather conditions in the PRD. The aerosol  
 331 DRF ( $\Delta F$ ) was calculated as the difference between the downward and upward radiation fluxes:

$$332 \quad \Delta F = F \downarrow - F \uparrow \quad (23) \text{3 Results and discussion}$$

### 333 3.1 Aerosol light absorption

334 The  $\text{AAE}_{\text{BC}}$  is widely defined as the uniform representation of the wavelength dependence of a

335 BC particle (Olson et al., 2015). In reality,  $AAE_{BC}$  may vary significantly with BC containing  
336 aerosols of different sizes, mixing states, and morphologies (Scarnato et al., 2013; Lack and  
337 Langridge, 2013). In fact, some studies showed that the AAE of a large-size, pure BC core may  
338 be less than 1.0 (Liu et al., 2018) and that the AAE of BC coated with a non-absorbing shell  
339 may be larger than that under uniformity (Lack and Cappa, 2010).

340 It has been suggested that a significant fraction of smaller size particles is non BC-containing  
341 (Ma et al., 2017; Cheung et al., 2016). BC and non-BC materials can also be externally or  
342 internally mixed. Although size resolved BC measurements were not available during this work,  
343 we have conducted size resolved Volatility Tandem Differential Mobility Analyzer (V-TDMA)  
344 measurements at 300°C for 40, 80, 110, 150, 200 and 300 nm, respectively, during an earlier  
345 field campaign (February 2014) at the same site as in this work. At 300°C, all non-BC particle  
346 will be completely vaporized (CV) and thus the portion of non BC particles at such size, denoted  
347 as  $\Phi_{N,CV}$ , can be determined. The average  $\Phi_{N,CV}$  values were 0.384, 0.181, 0.180, 0.158, 0.143  
348 and 0.137, corresponding to 40, 80, 110, 150, 200 and 300 nm, respectively (Cheung et al.,  
349 2016). For particle size larger than 300 nm and less than 40 nm,  $\Phi_{N,CV}$  values were set to 0.137  
350 and 0.384, respectively. Accordingly, the complete distribution of  $\Phi_{N,CV}$  for the whole PNSD  
351 was obtained. The mixing states of BC particles were also estimated here, i.e., the mass portion  
352 of externally mixed BC with respect to total BC, denoted as  $r_{ext}$ . The value of  $r_{ext}$  was taken as  
353 0.58, which was obtained using an optical closure method during a previous field experiment  
354 at this site (Tan et al., 2016a). During the following Mie theory calculation, a fixed refractive  
355 index ( $\tilde{m}_{core}=1.80-0.54i$ ,  $\tilde{m}_{non}=1.55-10^{-7}i$ ) was adopted for the whole size range. Accordingly,  
356 the calculated BC absorption at 880 nm ( $Abs_{880}$ ) was  $21.869 \text{ Mm}^{-1}$ , which is reasonably close  
357 to the measured mean value of  $21.199 \text{ Mm}^{-1}$ . To further validate our calculation scheme (Base  
358 Case), we have considered several extreme cases. Case 1: BC is completely externally mixed  
359 with non-BC particles, i.e.,  $\Phi_{N,CV} = 0$  and  $r_{ext} = 1$ ; Case 2: BC is present in every size bin and  
360 BC is completely internally mixed with non-BC material, i.e.,  $\Phi_{N,CV} = 0$  and  $r_{ext} = 0$ ; Case 3:  
361 BC is both internally and externally mixed but there is no non BC-containing particles, i.e.,  
362  $\Phi_{N,CV} = 0$  and  $r_{ext} = 0.58$ ; Case 4: BC is internally mixed with non-BC material and there is non-  
363 BC particles present, i.e.,  $\Phi_{N,CV}$  ranges from 0.384 to 0.137 and  $r_{ext} = 0$ ; Case 5: the same as  
364 case 4 except assuming a fixed non-BC to BC ratio of 0.5, i.e.,  $\Phi_{N,CV} = 0.5$ ,  $r_{ext} = 0$ ; Case 6: the

365 same as case 5 except that some externally mixed BC is also present, i.e.,  $\Phi_{N,CV} = 0.5$ ,  $r_{ext} =$   
366 0.58. The calculation results are listed in Table 1. Evidently, case 1 (complete externally mixed)  
367 will significantly underestimate the measured  $Abs_{880}$ , indicating that most BC particles were  
368 not likely externally mixed at the Panyu site. Complete internal mixing state (case 2, 4, and 5),  
369 on the contrary, would substantially overestimate the BC absorption regardless the form of BC  
370 core distribution function. However, when the  $r_{ext}$  were considered (case base, 3, and 6), the  
371 calculated  $Abs_{880}$  values were all very close to the measured value.

372 When the  $AAE_{BC}$  was assumed to be uniform, the campaign-averaged  $\sigma_{BrC}$  values were  
373  $17.6 \pm 13.7 \text{ Mm}^{-1}$  at 370 nm,  $9.7 \pm 7.9 \text{ Mm}^{-1}$  at 470 nm,  $5.8 \pm 5.1 \text{ Mm}^{-1}$  at 520 nm,  $4.0 \pm 3.5 \text{ Mm}^{-1}$  at  
374 590 nm and  $2.3 \pm 2.1 \text{ Mm}^{-1}$  at 660 nm. At the corresponding wavelengths, BrC absorption  
375 contributed  $26.2 \pm 8.5\%$ ,  $20.0 \pm 7.3\%$ ,  $14.3 \pm 6.5\%$ ,  $11.7 \pm 5.3\%$ , and  $7.8 \pm 4.1\%$  to the total aerosol  
376 absorption, respectively. When the  $AAE_{BC}$  was applied as the result of the Mie model  
377 calculation, the corrected campaign-averaged  $\sigma_{abs,BrC}$  values were  $23.5 \pm 17.7 \text{ Mm}^{-1}$  at 370 nm,  
378  $11.8 \pm 9.5 \text{ Mm}^{-1}$  at 470 nm,  $6.7 \pm 5.7 \text{ Mm}^{-1}$  at 520 nm,  $4.6 \pm 3.9 \text{ Mm}^{-1}$  at 590 nm and  $2.6 \pm 2.3 \text{ Mm}^{-1}$   
379 at 660 nm. At the corresponding wavelengths, BrC absorption contributed  $34.1 \pm 8.0\%$ ,  
380  $23.7 \pm 7.3\%$ ,  $16.0 \pm 6.7\%$ ,  $13.0 \pm 5.4\%$ , and  $8.7 \pm 4.3\%$  to the total aerosol absorption (see Fig. 2),  
381 respectively. Evidently, aerosol light absorption was predominantly due to BC; however, BrC  
382 also played a significant role, especially at shorter wavelengths. Table 2 shows the  
383 intercomparison of BrC light absorption in the near UV range between this work and other  
384 studies in the East Asian region. Clearly, the reported values vary substantially, and our result  
385 is toward the lower end of values.

### 386 **3.2 Uncertainty in BC and BrC optical differentiation**

387 Theoretically, the magnitude of BC absorptions can be affected by both parts of the complex  
388 refractive indexes (RIs); thus,  $AAE_{BC}$  may also vary with the RIs of both the BC core and  
389 coating shell. In fact, RI was also one of the least known properties of BC and other coating  
390 materials with negligible absorbing capabilities. The refractive index of the BC core ( $\tilde{m}_{core}$ )  
391 displays a wide range of variations (Liu et al., 2018). Typically, the real and imaginary parts of  
392 the RI can vary from 1.5 to 2.0 and 0.5 to 1.1, respectively. In addition, the shell was assumed  
393 to consist of non-absorbing material in the core-shell model, i.e., its imaginary RI was set to be  
394 close to zero ( $10^{-7}$ ). The real part of the non-absorbing material RI ( $\tilde{m}_{non}$ ) may vary from 1.35

395 to 1.6 due to the presence of OA (Zhang et al., 2018; Redmond and Thompson, 2011) and  
396 inorganic salts (Erlick et al., 2011). Hence, it is necessary to investigate the uncertainties  
397 associated with the variations in  $AAE_{BC}$  by varying the RIs of both the BC core and the non-  
398 absorbing materials.

399 Figure 3 shows the impacts of RI on the evaluations of  $AAE_{BC}$  based on core-shell and external  
400 configuration, where the RI of the BC core was set to be constant, i.e.,  $\tilde{m}_{core}=1.80-0.54i$ , and  
401 the real part of  $\tilde{m}_{non}$  varied from 1.35 to 1.6 at an interval of 0.05, with the imaginary part of  
402  $\tilde{m}_{non}$  set at  $10^{-7}$ . As shown in Fig. 3a, the calculated  $AAE_{BC}$  for the core-shell model was higher  
403 than 1.0 at longer wavelengths (520 to 880 nm) and lower than 1.0 at shorter wavelengths (370  
404 to 520 nm) (the red line in Fig. 3 denotes  $AAE_{BC}=1$ ). The averaged  $AAE_{BC,370-520nm}$  ranged from  
405 0.84 to 0.87, and the  $AAE_{BC,520-880nm}$  ranged from 1.07 to 1.15, indicating that the  $AAE_{BC,520-}$   
406  $880nm$  appeared to be more sensitive to the shell's real part than  $AAE_{BC,370-520nm}$ . Even if the shell  
407 material was assumed to be non-absorbing, the variation in the real RI of the shell, which was  
408 referred to as the real part of  $\tilde{m}_{non}$ , still led to changes in the shell's refractivity and  
409 correspondingly altered its lensing effect, causing a change in  $AAE_{BC}$ . Meanwhile,  $AAE_{BC,370-}$   
410  $520nm$  and  $AAE_{BC,520-880nm}$  generally increased with an increasing real part of the shell. In Fig. 3b,  
411 under the externally mixed conditions,  $AAE_{BC,370-520nm}$  and  $AAE_{BC,520-880nm}$  were both less than  
412 1.0. The average  $AAE_{BC,370-520nm}$  was 0.33, and the average  $AAE_{BC,520-880nm}$  was 0.63. These  
413 values were far less than the values under core-shell mixture conditions. In the external mixture  
414 model, the BC core and nonlight-absorbing materials were assumed to exist dependently, and  
415 then the optical properties of these two components were considered separately. Therefore,  
416 altering the real part of the externally mixed non-absorbing material would not affect the light  
417 absorption property of the BC core or  $AAE_{BC}$ .

418 The impacts of the BC core on  $AAE_{BC}$  are shown in Fig. 4, where the refractive index of  
419 nonlight-absorbing materials was assumed to be  $\tilde{m}_{non}=1.55-10^{-7}i$  and  $\tilde{m}_{non}$  was wavelength-  
420 independent. Fig. 4 was obtained with a core-shell mixture model (Fig. 4a and 4b) and an  
421 external mixture model (Fig. 4c and 4d) by varying the real part of  $\tilde{m}_{core}$  from 1.5 to 2.0 with  
422 a step of 0.05 and varying the imaginary part of the  $\tilde{m}_{core}$  from 0.4 to 1.0 with a step of 0.05,  
423 respectively. As shown in Figs. 4a and 4b, for the core-shell mixture, the averaged  $AAE_{BC,370-}$   
424  $520nm$  ranged from 0.55 to 0.99, and the averaged  $AAE_{BC,520-880nm}$  ranged from 0.84 to 1.27. The

425  $AAE_{BC}$  at a certain wavelength generally increased when increasing the real part of  $\tilde{m}_{core}$  but  
426 decreased when increasing the imaginary part of  $\tilde{m}_{core}$ . The  $AAE_{BC}$  appeared to be more  
427 sensitive to the imaginary part of  $\tilde{m}_{core}$  than the real part of  $\tilde{m}_{core}$  because the imaginary part  
428 of  $\tilde{m}_{core}$  was directly related to the light-absorbing properties of particles. In Fig. 4c and 4d,  
429 for the external mixture, the averaged  $AAE_{BC,370-520nm}$  ranged from 0.04 to 0.45 and the averaged  
430  $AAE_{BC,520-880nm}$  ranged from 0.28 to 0.79, while the averaged  $AAE_{BC,370-520nm}$  and  $AAE_{BC,520-}$   
431  $880nm$  were both less than 1.0. Similar to the core-shell mixture, the  $AAE_{BC,520-880nm}$  increased  
432 when increasing the real part of  $\tilde{m}_{core}$  but decreased when increasing the imaginary part of  
433  $\tilde{m}_{core}$ . However, the variation patterns of  $AAE_{BC,370-520nm}$  were different from those of  $AAE_{BC,520-}$   
434  $880nm$ . The  $AAE_{BC,370-520nm}$  values were not changed by altering the real part of  $\tilde{m}_{core}$  within the  
435 low imaginary part of  $\tilde{m}_{core}$ , whereas the  $AAE_{BC,370-520nm}$  values still increased when increasing  
436 the real part of  $\tilde{m}_{core}$  within the high imaginary part of  $\tilde{m}_{core}$ . A possible explanation was that  
437 the externally mixed BC core had weak light absorption within the low imaginary part of  $\tilde{m}_{core}$ ,  
438 causing the  $AAE_{BC,370-520nm}$  values to be insensitive to the real part of  $\tilde{m}_{core}$ . The  $AAE_{BC,520-}$   
439  $880nm$  values were higher than the  $AAE_{BC,370-520nm}$  values regardless of whether in they were for  
440 the core-shell mixture or external mixture. In addition, the  $AAE_{BC}$  values conducted by the  
441 core-shell mixture were higher than those conducted by the external mixture.

442 Figure 4 demonstrates that the variation in the imaginary RI of the BC core has the most  
443 significant impact on the estimated  $AAE_{BC}$ , indicating that the chemical component of BC  
444 emitted from different sources leads to a large uncertainty in  $AAE_{BC}$  estimation. At the same  
445 time, the influence arising from varying the real RI of the BC core was relatively moderate.  
446 Nevertheless, Fig. 3 demonstrated that change in the real RI of the non-absorbing materials  
447 caused the least/no impact compared to that caused by the variations in the complex RI of the  
448 BC core.

449 We want to note that most BC-containing particles are often observed as fractal rather than  
450 spherical in shape (Katrinak et al., 1993). Because the Mie model assumes that all particles are  
451 spherical, it may lead to potential uncertainty for the estimation of  $AAE_{BC}$  and BrC absorption  
452 contributions. Moreover, the externally mixed soot aggregates were “chain-like” or “puff-like”  
453 in the PRD dry season (Feng et al., 2010), in which the fractal dimension ( $D_f$ ) was between 1.5  
454 and 2.0. Coating soot aggregates were likely sphere ( $D_f$  approaches 3) from the high-resolution

455 transmission electron microscopy (TEM) measurements taken in Hongkong ((Zhou et al.,  
456 2014)). A soot aggregate sensitivity study with the superposition T-matrix method indicated  
457 that using the assumption of volume-equivalent spheres for the soot aggregates may result in  
458 an overestimation of approximately up to 15% and an underestimation of approximately up to  
459 50% in the predicted 870 nm light absorption when the  $D_f$  is between 1.5 and 3.0 (Liu et al.,  
460 2008). However, we should recognize the fact that different shapes or BC core positions may  
461 bring more difficult computational problems in practical numerical simulations. Applying the  
462 simplified Mie model would be a tradeoff scheme without particulate material morphological  
463 measurements in Panyu.

### 464 **3.3 Characteristics of BrC light absorption, water-soluble ions and OC concentrations**

465 Globally, BrC has been observed to be highly correlated with biomass and biofuel burning  
466 emissions (Laskin et al., 2015). Since large quantities of sylvite are present in biomass burning  
467 particles, the  $K^+$  abundance has often been used as a biomass burning tracer (Levine, 1991).  
468 Figure 5 presents the time series of the OC mass concentration,  $K^+$  concentration, and BrC  
469 absorption from 29 November 2014 to 2 January 2015 at the Panyu site. The range of the OC  
470 concentration obtained from the OC/EC online analyzer was from 1.5 to 65.2  $\mu\text{g cm}^{-3}$ , and the  
471 campaign average was  $12.5 \pm 7.3 \mu\text{g cm}^{-3}$ . The BrC absorption hourly mean data were between  
472 0.2 and 123.2  $\text{Mm}^{-1}$ , and the campaign average was  $23.5 \pm 17.7 \text{Mm}^{-1}$ . On the other hand, the  
473 average  $K^+$  concentration was  $1.0 \pm 0.7 \mu\text{g cm}^{-3}$  (ranging from 0 to 5.4  $\mu\text{g cm}^{-3}$ ). Clearly, similar  
474 trends among OC,  $K^+$ , and BrC absorption can be seen during this field campaign (Fig. 5).

475 To investigate the origins of these observed OC,  $K^+$ , and BrC, wind rose plots (as shown in Fig.  
476 6) were generated for OC,  $K^+$ , and BrC absorption, respectively. All three panels of Fig. 6  
477 consistently show that the three substances were associated with the same wind pattern. For the  
478 entire campaign period, the highest values of OC,  $K^+$ , and  $\sigma_{abs,BrC,370nm}$  were mostly associated  
479 with southwesterly winds with a relatively low wind speed ( $\sim 2 \text{ m s}^{-1}$ ). The relatively higher OC  
480 and  $K^+$  concentrations were highly related to the seasonal straw burning in the countryside of  
481 the PRD located to the west of the Panyu station. In contrast, OC and  $K^+$  concentrations during  
482 periods with easterly winds were substantially lower than those during periods with westerly  
483 winds. The wind rose plot of  $\sigma_{abs,BrC,370nm}$  is shown in Fig. 6c. Similar to OC and  $K^+$ ,  $\sigma_{abs,BrC,370nm}$   
484 showed higher values under weak ( $< 2 \text{ m s}^{-1}$ ) westerly winds and lower values from the north

485 and south, indicating that BrC absorption was likely attributed to local sources and was  
486 accumulated under calm wind conditions. However, there was a detectable difference among  
487 the three rose plots in the maximum concentration direction. A possible explanation was that  
488 although biomass burning emissions were believed to be the dominant and primary source of  
489 OC, K<sup>+</sup>, and BrC, their emission ratios were highly variable and may change with the type of  
490 biofuel and burning condition and may even vary during different stages of burning (Burling et  
491 al., 2012). Although biomass burning emissions contain substantial light-absorbing BrC,  
492 further atmospheric aging processes may significantly reduce its light-absorbing capability  
493 (Satish et al., 2017). Moreover, secondary formation may also lead to BrC formation inside  
494 these primary aerosols, such as humic-like substances formed through aqueous-phase reactions,  
495 which have been suggested to be an important component of BrC (Andreae and Gelencser,  
496 2006).

497 To further explore the possible sources of BrC optical absorption, the diurnal variations in OC,  
498 K<sup>+</sup>,  $\sigma_{abs,BrC,370nm}$ , and  $\sigma_{abs,BrC,370nm}/OC$  values are plotted in Fig. 7. The diurnal variation in OC  
499 at the Panyu site appeared to be dominated by the development of the planetary boundary layer  
500 (PBL) height, i.e., primary emissions accumulated at night and were swiftly diluted by vertical  
501 mixing in the morning. The slight increase in OC in the afternoon indicated that photochemistry  
502 may have still weakly contributed to SOA formation. Figure 7b shows the diurnal variation in  
503 K<sup>+</sup>. Unlike OC, K<sup>+</sup> shows a small peak at approximately 6 AM, which was consistent with  
504 breakfast time and was very likely due to cooking activities using biofuel. No lunch and dinner  
505 time K<sup>+</sup> peaks were observed. The most likely explanation is that the boundary layer height is  
506 much higher during lunch and dinner time than in the early morning, providing a much better  
507 atmospheric diffusion condition for air pollutants. It is still a common practice to collect straw  
508 as biofuel in local rural areas, which can be visually spotted but is not heavily utilized in the  
509 region. However, the diurnal profile of  $\sigma_{abs,BrC,370nm}$  (see Fig. 7c) shows the combined features  
510 of OC and K<sup>+</sup> since both primary and secondary processes affect its intensity. The nighttime  
511 increasing trend was most likely attributed to straw burning activities in early winter in nearby  
512 rural areas that continued to accumulate within the shallow PBL (Jiang et al., 2013).  
513  $\sigma_{abs,BrC,370nm}/OC$ , i.e., the mass absorption coefficient of BrC (MAC<sub>BrC</sub>) (Fig. 7d), showed a  
514 relatively flat pattern, with a pronounced dip in the afternoon and higher values at nighttime,

515 which was likely due to enhanced primary emissions and stable stratification at nighttime.  
516 Declining trends during the late morning and afternoon hours indicated that the aging process  
517 and photochemical production may reduce the light-absorbing capacity of BrC (Qin et al.,  
518 2018).

519 Furthermore, Fig. 8 shows the linear regression analysis results used to evaluate the correlations  
520 of  $\sigma_{abs,BrC,370nm}$  with the OC,  $K^+$ ,  $Ca^{2+}$ ,  $Mg^{2+}$ ,  $Cl^-$ ,  $SO_4^{2-}$ ,  $NO_3^-$ , and  $NH_4^+$  concentrations. The best  
521 correlations can be found between  $\sigma_{abs,BrC,370nm}$  and  $K^+$  ( $R^2=0.6148$ ), followed by those between  
522  $\sigma_{abs,BrC,370nm}$  and OC ( $R^2=0.4514$ ),  $NO_3^-$  ( $R^2=0.4224$ ) and  $NH_4^+$  ( $R^2=0.4656$ ). Source  
523 apportionment analysis of OA and BrC absorption in Beijing and Guangzhou illustrated that  
524 biomass burning organic aerosols (BBOAs) correlated well with BrC light absorption (Xie et  
525 al., 2018; Qin et al., 2018). Thus, the significant correlation between BrC absorption and  $K^+$   
526 reaffirmed that biomass burning was the crucial emission source of BrC observed in this work.

527 Although the geographic location of the observation site was situated in a coastal area and  $K^+$   
528 could also be found in sea salt (Pio et al., 2008), it should be noted that the prevailing wind  
529 direction during winter was from the north (see Fig. 3), which drives maritime air parcels away  
530 from the site. Hence, the effect of sea salt and crustal materials to  $K^+$  was slight, which was  
531 demonstrated in the supplementary information as shown in Fig. S1. Other earlier studies also  
532 suggested that the sea salt contribution to the  $K^+$  concentrations of  $PM_{2.5}$  was trivial in the PRD  
533 region during the winter (Lai et al., 2007). Another possible  $K^+$  source was coal combustion.

534 The coal consumption in the PRD region was dominated by coal-fired power plants. The  
535 emission from power plants was usually very steady and was less likely to affect the diurnal  
536 correlation between  $K^+$  and BrC absorption. As shown in Fig. 9, the ratios of  $K^+/PM_{2.5}$  varies  
537 approximately from 0.015 and 0.020 and the diurnal profile of  $K^+/PM_{2.5}$  shows very little  
538 variation. Yu et al. (2018) have suggested that  $K^+$  usually accounted for 2.34-5.49% of  $PM_{2.5}$  in  
539 the laboratory biomass burning study. However,  $K^+$  was normally lower than 1% of coal  
540 combustion  $PM_{2.5}$ . Therefore, the ratio range of  $K^+$  to  $PM_{2.5}$  observed in this work likely  
541 indicated aged biomass burning particles. Both nitrogen oxides ( $NO_x$ ) and ammonia ( $NH_3$ ) can  
542 be found in biomass burning plumes (Andreae and Merlet, 2001). For  $NO_3^-$  and  $NH_4^+$ , nitrate  
543 can be converted from  $NO_x$  through atmospheric reactions, and ammonium may originate from  
544  $NH_3$ . However, similar to the diurnal variation in  $\sigma_{abs,BrC,370nm}$ , diurnal variations in  $NH_4^+$  and

545  $\text{NO}_3^-$  also increased in the afternoon and appeared at nighttime in Fig 9. However,  $\text{NO}_3^-/\text{PM}_{2.5}$   
546 and  $\text{NH}_4^+/\text{PM}_{2.5}$  reached their peaks at noon, indicating that ammonium nitrate formed from the  
547 secondary reaction at this time. Along with the reduced boundary layer height and ambient  
548 temperature,  $\text{NO}_3^-$  was accumulated until the photochemical reaction stopped at night. The  
549 diurnal variation in  $\text{NH}_4^+$  was similar to that in  $\text{NO}_3^-$  due to the acid/base neutralization reaction.  
550 The overlapping of the  $\sigma_{\text{abs,BrC},370\text{nm}}$ ,  $\text{NH}_4^+$  and  $\text{NO}_3^-$  diurnal variations would lead to a significant  
551 correlation between BrC absorption and  $\text{NO}_3^-$  or  $\text{NH}_4^+$ . High concentrations of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$   
552 are often found in dust-related aerosols (Lee et al., 1999).  $\sigma_{\text{abs,BrC},370\text{nm}}$  showed poor correlations  
553 with both  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ , indicating that dust-related aerosol components contribute  
554 insignificantly to the total aerosol mass loading and, thus, dust may not affect the AAE  
555 differentiation method used in this work. Although sulfur dioxide ( $\text{SO}_2$ ) may also be emitted by  
556 biomass burning,  $\text{SO}_4^{2-}$  is often believed to be secondary in nature, and the presence of other  
557 intense  $\text{SO}_2$  sources (e.g., automobile and industrial emissions) further reduces the correlation  
558 between BrC and  $\text{SO}_4^{2-}$ . Sources of  $\text{Cl}^-$  include both combustion and sea salt spray (Waldman  
559 et al., 1991). Although the prevailing wintertime wind direction was from the north, sea salt  
560 can still be carried to the site by a weak sea breeze, and thus,  $\text{Cl}^-$  may not show considerable  
561 correlation with BrC.

### 562 **3.4 BrC radiative forcing efficiency**

563 The radiative effects of aerosol scattering, BrC absorption, and BC absorption were investigated  
564 by the SBDART model. For each investigated variable under cloud-free conditions, we run the  
565 model twice to calculate the DRF at the TOA with and without the investigated variable.  
566 Accordingly, the difference of  $\Delta F$  between the two simulations was considered as the radiative  
567 effect of the investigated variable. The results showed that the average radiative forcings at the  
568 TOA by scattering, BrC absorption, and BC absorption were  $-21.4 \pm 5.5 \text{ W m}^{-2}$ ,  $2.3 \pm 1.8 \text{ W m}^{-2}$ ,  
569 and  $10.9 \pm 5.1 \text{ W m}^{-2}$ , respectively. Furthermore, BrC absorption was attributed to  $15.8 \pm 4.4\%$   
570 of the warming effect caused by aerosol light absorption, demonstrating the nonnegligible role  
571 of BrC in radiative forcing evaluation.

572 We also calculated the BrC radiative forcing efficiency (RFE) under various *SSA* (ranging from  
573 0.7 to 0.99) at three wavelengths, i.e., 440 nm, 675 nm, and 870 nm. The RFE was denoted as  
574 the radiative forcing normalized by the AOD. The average AOD and ASY at the three

575 wavelengths were 0.365 and 0.691 at 440 nm, 0.212 and 0.632 at 675 nm, and 0.154 and 0.619  
576 at 870 nm, respectively. A solar zenith angle of  $55^\circ$  and an average shortwave broadband surface  
577 albedo (0.119) were used in the calculation. The results were plotted as a set of RFE lookup  
578 charts as a function of the surface BrC absorption contribution (see Fig. 10).

579 In general, for any wavelength, the RFE increased with increasing BrC absorption contribution  
580 for a certain *SSA*, indicating that BrC was a more efficient radiative forcing agent due to the  
581 preferential absorbance of BrC in a shorter wavelength range. However, for a certain BrC  
582 absorption contribution, the RFE increased with decreasing *SSA*, i.e., a higher portion of light-  
583 absorbing aerosol components can lead to more efficient radiative forcing. The trend among  
584 panels (a), (b), and (c) in Fig. 10 demonstrated that the effect of BrC absorption contribution  
585 on RFE was wavelength-dependent, i.e., BrC was a weaker radiative forcing agent at longer  
586 wavelengths, which is also consistent with the wavelength-dependent light-absorbing property  
587 of BrC. The red stars in Fig. 10 denote the average *SSA* and BrC absorption contribution  
588 conditions during this campaign, i.e.,  $0.029 \text{ W m}^{-2}$  per unit AOD at 440 nm (Fig. 10a),  $0.007$   
589  $\text{W m}^{-2}$  per unit AOD at 675 nm (Fig. 10b), and  $0.0002 \text{ W m}^{-2}$  per unit AOD at 870 nm (Fig.  
590 10c). These results suggested that the average value of RFE decreased distinctly from 440 nm  
591 to 870 nm not only because of the lower BrC absorption contribution but also because of the  
592 wavelength-dependence of the BrC RFE. It should also be noted that the simulations were based  
593 on *SSA* measured under dry conditions. Under the typical ambient conditions of the PRD, the  
594 *SSA* might be markedly enhanced by aerosol water uptake (Jung et al., 2009), and then, the BrC  
595 radiative forcing efficiency might be less. Moreover, Fig. 10 also serves as a lookup table to  
596 conveniently assess the BrC radiative forcing efficiency at different wavelengths with different  
597 BrC absorption contributions for a certain *SSA*.

#### 598 **4 Conclusion**

599 In this work, light absorption due to BrC in the PRD region of China was quantitatively deduced  
600 during the winter season of 2014. Using the absorption coefficients of BC calculated according  
601 to the Mie theory and the observed total aerosol absorption coefficients, we estimated the  
602  $\text{AAE}_{\text{BC}}$  and hence the BrC absorption contribution for the optically equivalent mixture  
603 configuration. The average BrC light absorption contribution ranged from  $8.7 \pm 4.3\%$  at 660 nm  
604 up to  $34.1 \pm 8.0\%$  at 370 nm when  $\text{AAE}_{\text{BC}}$  was set as uniform. The sensitivity of  $\text{AAE}_{\text{BC}}$

605 estimation associated with different RI and mixing state assumptions was further investigated.  
606 The results showed that variations in the real RI of the non-absorbing material (1.35 to 1.6) may  
607 decrease  $AAE_{BC,370-520nm}$  from 0.84 to 0.87 and  $AAE_{BC,520-880nm}$  from 1.07 to 1.15 for core-shell  
608 mixtures, with an  $AAE_{BC,370-520nm}$  of 0.33 and  $AAE_{BC,520-880nm}$  of 0.63 for external mixtures.  
609 Variations in the core's real RI (1.5 to 2.0) and imaginary RI (0.4 to 1.0) may reduce  $AAE_{BC,370-}$   
610  $520nm$  from 0.55 to 0.99 and  $AAE_{BC,520-880nm}$  from 0.84 to 1.27 for the core-shell mixture and  
611 reduce  $AAE_{BC,370-520nm}$  from 0.04 to 0.45 and  $AAE_{BC,520-880nm}$  from 0.28 to 0.79 for the external  
612 mixture. These results indicate that the optical properties of the BC core and non-absorbing  
613 material can significantly affect the accuracy of  $AAE_{BC}$  and corresponding BrC absorption  
614 contribution estimations.

615 Additionally, the measurements of major water-soluble inorganic ions (including  $K^+$ ,  $NO_3^-$ , and  
616  $NH_4^+$ ) and particulate OC showed consistent features with those of  $\sigma_{abs,BrC,370nm}$ , implying that  
617 BrC was associated with biomass-burning emissions from nearby rural areas. Moreover, the  
618 diurnal trend in  $\sigma_{abs,BrC,370nm}/OC$  indicated that primary biomass burning emissions can produce  
619 intense light-absorbing BrC, while the photochemical aging process may weaken the light-  
620 absorbing capability of BrC.

621 Using a radiative transfer model (i.e., SBDART), we estimated the BrC effects on aerosol  
622 radiative forcing. The average shortwave aerosol direct radiative forcings due to scattering, BrC  
623 absorption, and BC absorption at the TOA were evaluated to be  $-21.4 \pm 5.5 \text{ W m}^{-2}$ ,  $2.3 \pm 1.8 \text{ W}$   
624  $\text{m}^{-2}$ , and  $10.9 \pm 5.1 \text{ W m}^{-2}$ , respectively. BrC absorption accounted for  $15.8 \pm 4.4\%$  of the total  
625 shortwave solar absorption warming effect at the TOA, indicating that BrC might be an  
626 important climate forcing agent, which is largely neglected in current climate models. To  
627 facilitate the estimation of the climate effects of BrC, a set of look-up charts was constructed  
628 for the investigated area based on the default tropical atmosphere profile, average surface  
629 albedo, average asymmetry factor, and surface-measured aerosol properties (i.e., BrC  
630 absorption contribution,  $SSA$ , and AOD). Therefore, the role of the BrC radiative forcing  
631 efficiency at three wavelengths can be conveniently assessed for certain  $SSA$  and BrC  
632 absorption contributions.

633

634 *Author contributions*

635 HT, JZ, YM, and CC designed the experiments, and ZL, LL, YQ, NW, FL, YL, and MC carried  
636 out the field measurements and data analysis. ZL and YQ performed Mie theory simulation.  
637 ZL, JZ, and HT prepared the manuscript with comments from all coauthors.

638

891 **Table 1.** Inter-comparison of the performance of various Mie-calculation schemes. The base  
892 case is based on the empirical distribution function and mixing states of BC particles obtained  
893 from previous field measurements at the same site.  $\Phi_{N,CV}$  denotes the portion of non-BC  
894 particles and  $r_{ext}$  is the mass portion of externally mixed BC with respect to total BC.  $AAE_{BC}$  is  
895 the absorption Ångström exponent of BC, and the subscript represents the wavelength range.  
896  $Abs_{BrC,370\%}$  and  $Abs_{BrC,520\%}$  are the BrC absorption contributions at 370 nm and 520 nm,  
897 respectively.  $Calcabs_{880}$  is the calculated absorption at 880 nm using Mie model.  $Measabs_{880}$  is  
898 the measured absorption by an Aethalometer at 880 nm.  $b$  is the intercept of the regression  
899 analysis between  $Measabs_{880}$  and  $Calcabs_{880}$ , i.e.,  $Calcabs_{880}=b * Measabs_{880}$ .  $R^2$  is the  
900 correlation coefficient of the equation. The refractive index of BC core ( $\tilde{m}_{core}$ ) and nonlight-  
901 absorbing particles ( $\tilde{m}_{non}$ ) is set to be 1.80-0.54i and 1.55-10<sup>-7</sup>i, respectively (Tan et al., 2016a),

Case #	Scheme	$\Phi_{N,CV}$	$r_{ext}$	AAE	AAE	Abs	Abs	Calc	Meas	b	$R^2$

Jan. 2012	Nagoya (Japan)	405	Not detected	11% (300°C) 17% (400°C)	Thermometer r PASS-3	(Nakayama et al. (2015))

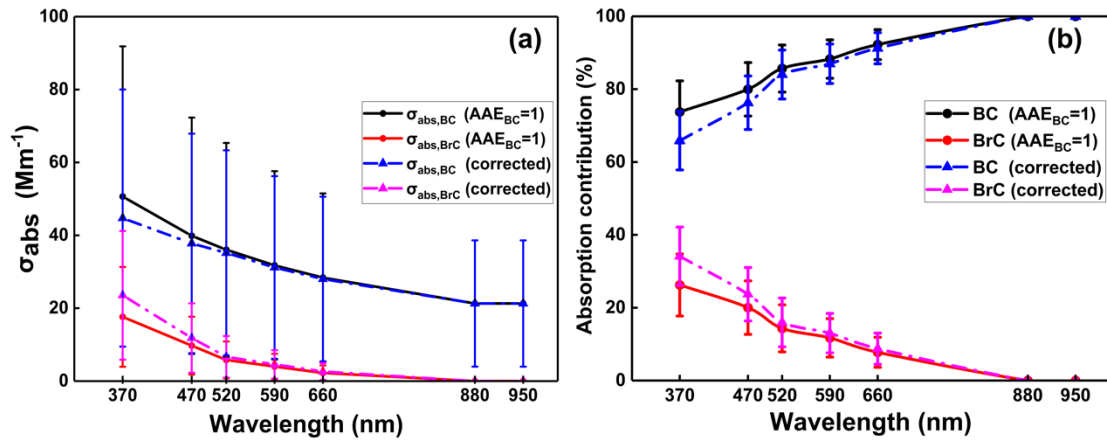

908

909 Figure 1. The location of Panyu station (CAWNET) in the PRD region (indicated by the red

910 dot). The plain areas within the yellow circles are the main rural areas of western PRD.

911

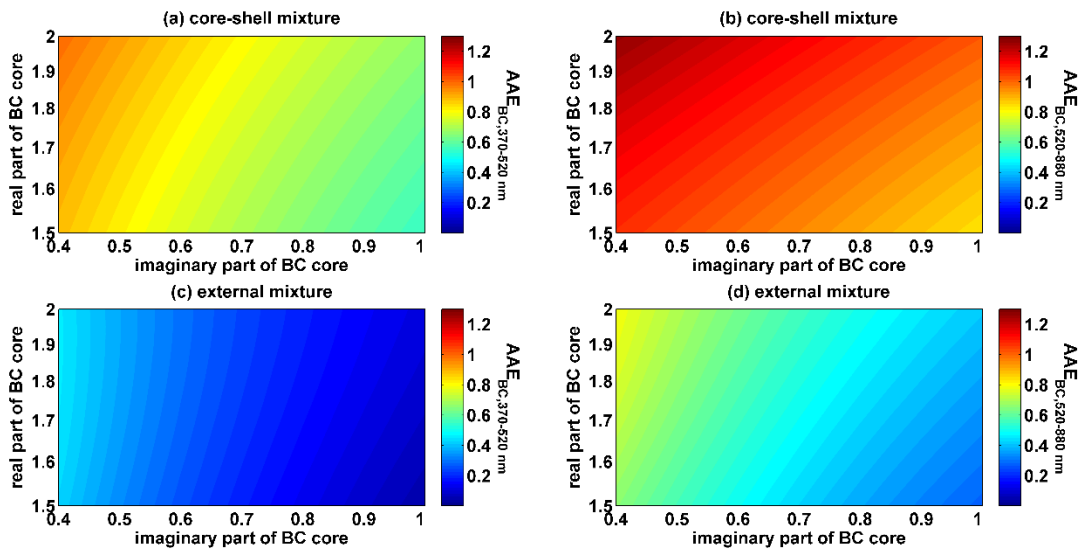

913

914 Figure 2. (a) BC and BrC particle average light absorption coefficients at different  
 915 wavelengths under different AAE<sub>BC</sub> assumptions; the whiskers represent an error of  
 916 one standard deviation. (b) Contributions of BC and BrC to the total light absorption  
 917 coefficient at different wavelengths under different AAE<sub>BC</sub> assumptions; the whiskers  
 918 represent an error of one standard deviation.

919

920 Figure 3. Influence of the wavelength-independent refractive index of the non-  
 921 absorbing materials on the (a) AAEs of the core-shell mixture and (b) AAEs of the  
 922 external mixture with a constant BC core refractive index ( $\tilde{m}_{core}=1.80-0.54i$ ). The  
 923 imaginary part of the non(less)-absorbing shell was set to  $10^{-7}$ , while the real part varied  
 924 from 1.35 to 1.60. In each panel, the boundaries of the box represent the 75th and 25th  
 925 percentiles; the whiskers above and below each box indicate an error of one standard  
 926 deviation; the black lines in the boxes denote the average values. In panels a and b, the  
 927 red line indicates where  $AAE_{BC}=1$ .  
 928

930

931 Figure 4. Influence of the wavelength-independent refractive index of the BC core on  
 932 AAEs with a constant shell refractive index ( $\tilde{m}_{shell}=1.55-10^{-7}i$ ). A core-shell mixture  
 933 was used for panels a and b, and an external mixture was used for panels c and d. The  
 934 real part of  $\tilde{m}_{core}$  varied from 1.5 to 2.0, with a step of 0.05, and the imaginary part of  
 935  $\tilde{m}_{core}$  varied from 0.4 to 1.0, with a step of 0.05.

936

937

938 Figure 5. Time series of the OC aerosol mass concentration (green line), water-soluble  $\text{K}^+$  mass

939 concentration (blue line), and BrC light absorption (red line).

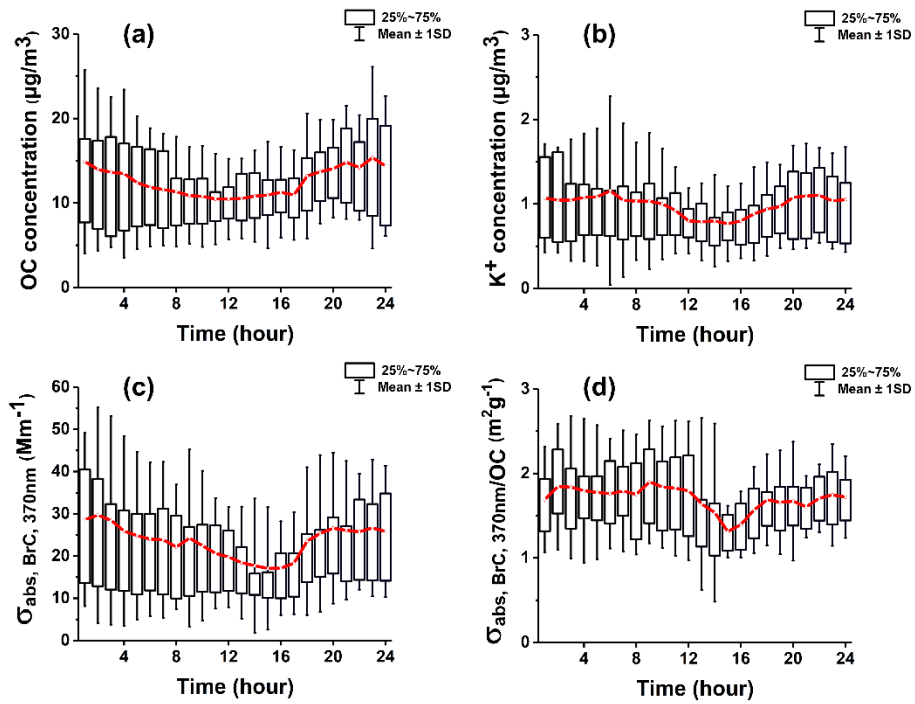

940

942

943 Figure 6. Wind rose plots of OC (a),  $\text{K}^+$  (b), and  $\sigma_{\text{abs, BrC, 370nm}}$  (c). In each panel, the black solid  
944 lines denote the frequency of the wind direction. The shaded contour represents the average  
945 values of the corresponding species for that wind speed (radial length) and wind direction  
946 (transverse direction) in polar coordinates.

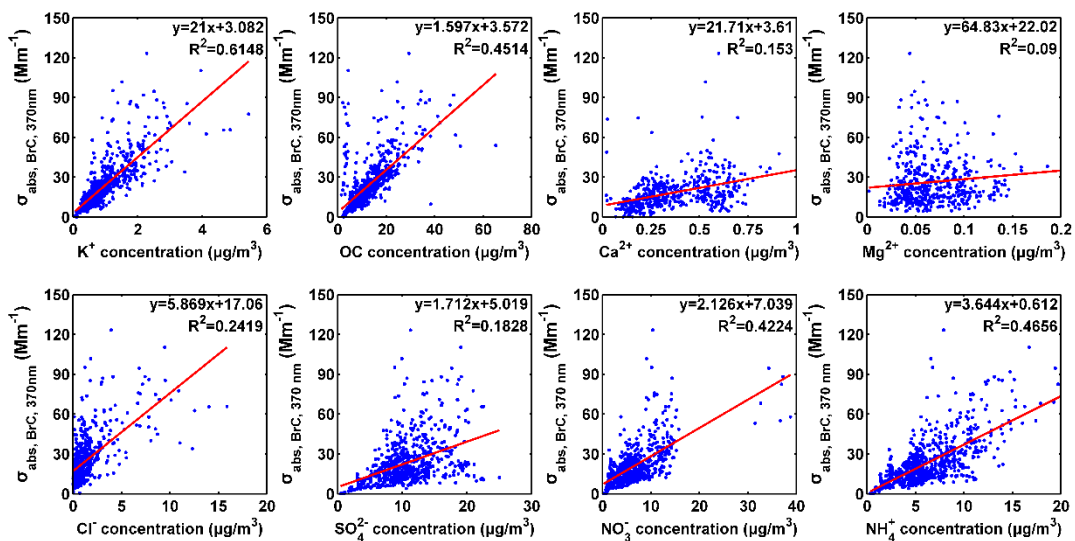

947

949

950 Figure 7. Box-whisker plots of diurnal trends in the OC concentration (a), water-soluble  $\text{K}^+$   
 951 concentration (b),  $\sigma_{\text{abs,BrC,370nm}}$  (c), and  $\sigma_{\text{abs,BrC,370nm}} / \text{OC}$  (d). The red traces represent the  
 952 variation in the average value. The upper and lower boundaries of the box represent the 75th  
 953 and 25th percentiles, respectively; the whiskers above and below each box represent an error  
 954 of one standard deviation.

955

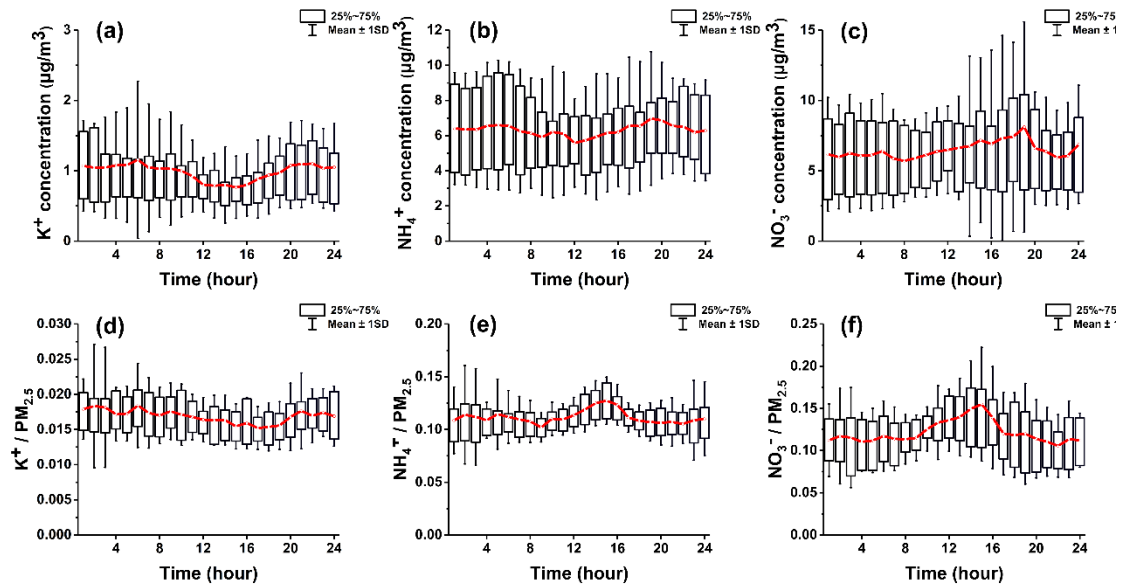

956

957 Figure 8. Correlations of the BrC absorption coefficient at 370 nm with OC, water-soluble  $\text{K}^+$ ,

958  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ , and  $\text{NH}_4^+$  aerosol concentrations.

959

960 Figure 9. Box-whisker plots of diurnal trends in  $K^+$  concentration (a),  $\text{NH}_4^+$  concentration (b),

961  $\text{NO}_3^-$  concentration (c),  $K^+/\text{PM}_{2.5}$  (d),  $\text{NH}_4^+/\text{PM}_{2.5}$  (e) and  $\text{NO}_3^-/\text{PM}_{2.5}$  (f). The red traces

962 represent the variation in average value. The upper and lower boundaries of the box represent

963 the 75th and 25th percentiles, respectively; the whiskers above and below each box represent

964 an error of one standard deviation.

965

966

968

969 Figure 10. BrC radiative forcing efficiencies, which are defined as the BrC TOA direct radiative  
 970 forcing divided by the AOD, as a function of the BrC to BC absorption ratio and *SSA* measured  
 971 at the surface. The average AOD of the three wavelengths, the average ASY of the three  
 972 wavelengths, a solar zenith angle of  $55^\circ$ , and average shortwave broadband surface albedo were  
 973 used in the calculation. The red star corresponds to the average *SSA* and BrC absorption  
 974 contributions determined from this campaign.
