14 **Abstract**

15 Intense new particle formation (NPF) events were observed in the coastal atmosphere during algae growth and  
16 farming season at Xiangshan Gulf of east China coast. High nucleation-mode iodine concentrations measured by  
17 ultra-performance liquid chromatography coupled with quadruple time-of-flight mass spectrometry  
18 (UPLC/Q-TOF-MS) confirmed that the NPF events were induced by iodine species. Farmed microalgae, as well as  
19 wild algae, could be an important NPF source in coastal areas of China. For the first time, we identified 5 inorganic  
20 iodine species, 45 organic iodine compounds (35 molecular formulas) and a group of iodide-organic adducts in  
21 ambient aerosols. The concentrations and size distributions of iodine species down to 10 nanometers were

22 measured during the iodine-induced NPF, continental NPF and non-NPF days at the coastal site and compared to  
23 those at an inland site. The iodine in the above four types of aerosol samples were characterized by iodate, aromatic  
24 iodine compounds, iodoacetic acid/iodopropenoic acid and iodide-organic adducts, respectively. This study sheds  
25 light on the iodine sources, formation mechanism and its contribution to the coastal NPF in the context of heavy air  
26 pollution in eastern China.

27

## 28 1. Introduction

29 Iodine is an essential trace element for all mammals (including human being) and some aquatic plants. In the  
30 atmosphere, iodine plays an important role in ozone ( $O_3$ ) depletion, altering HOx and NOx chemistry, mercury  
31 oxidation and aerosol formation (Baker et al., 2001; O'Dowd et al., 2002). Marine emission sources of iodine  
32 containing species in the atmosphere, such as iodomethane, molecular iodine ( $I_2$ ), hypiodous acid (HOI) include  
33 marine biota emission (Baker et al., 2000), sea surface iodide ( $I^-$ ) activation by  $O_3$  (Dixneuf et al., 2009; Mcfiggans  
34 et al., 2004; Palmer et al., 2005; Sellegri et al., 2006) and sea surface bubble bursting (Seto and Duce, 1972).  
35 Continental iodine sources include soil emission, fossil fuel and biomass combustions and industrial emissions  
36 (Redeker et al., 2000; Sive et al., 2007). In recent years, much attention has been paid to the new particle formation  
37 (NPF) induced by iodine species (Dall'Osto et al., 2018; Allan et al., 2015; Roscoe et al., 2015; Mahajan et al., 2011;  
38 McFiggans et al., 2010; O'Dowd and De Leeuw, 2007; Grose et al., 2007; Yoon et al., 2006; O'Dowd et al., 2002).  
39 Based upon current knowledge, a simplified scheme of iodine oxidation and nucleation is described as follows:  
40 volatile iodocarbons or  $I_2$  photolyses to I atoms, which react with  $O_3$  to produce IO and  $IO_2$  radicals; subsequently  
41 the self-combination of IO and  $IO_2$  forms iodine oxides  $I_2O_{2.5}$ ; iodine oxoacids  $HIO_x(x=1-3)$  were produced either  
42 from  $I_2O_{2.5}$  hydration or via the reaction of IO and  $IO_2$  reaction with  $HO_x$  (Burkholder et al., 2004; Martín et al.,

43 2013; Sipil *et al.*, 2016); eventually, the clustering of  $I_2O_{2.5}$  or  $HIO_x$  and the subsequent growth of these ultrafine  
44 iodide particles contribute to cloud condensation nuclei (CCN) so as to influence the climate.

45 In the past, iodine concentration or speciation has been measured in natural and drinking water (Chen *et al.*,  
46 2007; Liu *et al.*, 2015; Wang and Jiang, 2008; Wei *et al.*, 2007), precipitation (Gilfedder *et al.*, 2007a; Yoshida *et al.*,  
47 2007), soil (Yoshida *et al.*, 2007), animal and microalgae tissues (Hughes *et al.*, 2006; Kaňa *et al.*, 2015; Shah *et al.*,  
48 2005), edible salts (Yun *et al.*, 2017; Zhang *et al.*, 2010), and milk (Wang and Jiang, 2008). Previous measurements  
49 in ambient aerosols showed only three iodine species:  $I^-$ , iodate ( $IO_3^-$ ) and total soluble organic iodine (SOI) and  
50 their relative concentration and size distribution varied largely with locations (e.g. inland, coastal or open ocean)  
51 (Baker *et al.*, 2001; Gilfedder *et al.*, 2007a, b; Lai *et al.*, 2008; Wimschneider and Heumann, 1995; Xu *et al.*, 2010).  
52 The majority of atmospheric models assume that  $IO_3^-$  would be the only stable iodine species in aerosols  
53 (Saiz-Lopez *et al.*, 2012), because  $I^-$  may be eventually oxidized to  $IO_3^-$  in aerosols or participate in halogen  
54 activation to yield gaseous IX (X=Cl, Br, I). SOI seems to be formed from the reaction of aerosol organic matter  
55 with HOI (Baker, 2005b). Organic iodine compounds are more toxic than  $I^-$  and  $IO_3^-$  to humans (Ding and Zhang,  
56 2009) and may play a key role in regulating the recycling of halogens to the gas phase. At present the speciation of  
57 organic iodine compounds is the most significant unknowns in aerosol iodine chemistry (Saiz-Lopez *et al.*, 2012).  
58 Hence, to study the iodine speciation and size distribution will surely help to understand their sources,  
59 transformation mechanisms and deposition rates in the atmosphere.

60 It still poses a challenge to determine organic iodine compounds in ambient aerosol. Up to date, there is no  
61 detailed aerosol organic iodine speciation study in the literature. Total SOI was generally calculated as total soluble  
62 iodine minus inorganic  $I^-$  and  $IO_3^-$  (Lai *et al.*, 2008), which can be separated and quantified using an ion  
63 chromatography coupled with inductively coupled plasma mass spectrometry (IC-ICP-MS). Although the peaks in  
64 IC other than  $I^-$  and  $IO_3^-$  were suspected to be organic iodine (Gilfedder *et al.*, 2007a, b, 2008), ICP-MS did not

65 provide molecular weight information. Without foreknown information of ion mass, molecular structure or  
66 retention time (RT), neither liquid chromatography-MS (LC-MS) nor gas chromatography MS (GC- MS) can be  
67 applied to identify and quantify unknown organic iodine in the aerosols. Unlike those in disinfection by-products or  
68 iodine-rich seaweed, individual organic iodine compound in a complex aerosol matrix is of extremely low  
69 concentration. Based on our experience, organic iodine ions co-elute with many other interfering ions even after  
70 chromatographic separation. As a result, it is difficult to apply even high resolution mass spectrometry to identify  
71 unknown organic iodine compounds in the aerosols using MS and MS/MS experiments.

72 The populated coastal regions of eastern China are influenced by both industrial and marine emissions.  
73 Growing algae population due to serious eutrophication in the coastal waters may promote iodine emission, which  
74 make the coastal region a potential hotspot of new particle formation. Up to now, there has been no report of iodine  
75 induced NPF in the places out of coastal sites of west Europe (e.g., Mace Head, Ireland; Roscoff, France; O Grove,  
76 Spain), Tasmania (Cape Grim) and Polar regions. Besides, the iodine speciation measurement in particles smaller  
77 than 100 nm is also scarce (Baker, 2005a; Baker, 2004; Gilfedder et al., 2008; Lai et al., 2008; Wimschneider and  
78 Heumann, 1995). The purpose of our study is to characterize iodine speciation using the ultra-performance liquid  
79 chromatography coupled with quadruple time-of-flight mass spectrometry (UPLC/Q-TOF-MS) and measure their  
80 concentrations in size segregated particles down to 10 nm diameter collected during the NPF events observed at a  
81 coastal site of China. The comparison of iodine species between the coastal site and an inland site will also be  
82 discussed.

## 83 2. Experiments

### 84 2.1 Sampling

85 A five-month campaign from January to May 2018 was carried out at Xiangshan Gulf of Zhejiang Province on

86 the east coast of China. The coastal observation site (29 °29'N, 121 °46'E, see Figure 1) is a small building about  
87 40m and 200m away from the coastline at high tide and low tide, respectively. The Xiangshan Gulf is developed as  
88 the largest algae cultivation area of Zhejiang Province. This feature makes the Xiangshan Gulf a potential hotspot  
89 of iodine emission from wild or farmed microalgae. We used a scanning mobility particle spectrometer (SMPS) and  
90 a Neutral Air Ion Spectrometer (NAIS) to monitor NPF events at the site. The statistical characteristics of new  
91 particle formation at the observation site are not the focus of this paper. Instead, a nano Micro-Orifice Uniform  
92 Deposit Impactor (nano-MOUDI, MSP Corp, Shoreview, MN) or a median-volume aerosol sampler were used to  
93 collect size segregated 10 nm -18 µm aerosols or PM<sub>2.5</sub> during typical NPF days. The 13-stage nano-MOUDI  
94 provides cut sizes of 18, 10, 5.6, 3.2, 1.8, 1.0, 0.56, 0.32, 0.18, 0.10, 0.056, 0.032 and 0.010 µm in aerodynamic  
95 diameters when operating at a flow rate of 30 L min<sup>-1</sup>. Offline method by high resolution mass spectrometer was  
96 developed to analyze iodine in the aerosol samples.

97 Particle size distribution from 2 nm to 740 nm was obtained by integrating a long SMPS (TSI DMA3081 and  
98 CPC3775; scanning range: 40–750nm) and NAIS (scanning range:2–42nm) data. The SMPS sampled ambient air  
99 from a 129cm long and 1.0 cm inner diameter (I.D.) SS tube horizontally oriented with an airflow of 14 standard  
100 L min<sup>-1</sup>. NAIS sampling inlet was a 1.5 m long and 32 cm inner diameter copper tube. The transport loss of  
101 particles in the SMPS and NAIS inlets was corrected using size-dependent survival ratios. Scanning cycles of the  
102 SMPS and NAIS were synchronized to 4 minutes. The NAIS measured positive ion, negative ion and total particles  
103 alternately. Based on the particle size distribution data, we found that unless it was cloudy or rainy, strong NPF  
104 events were observed almost every day in April and May, which is the growth and farming season of seaweed. As  
105 would be discussed in Section 3, high nucleation-mode iodine concentration suggests these NPF events were  
106 induced by iodine (hereafter, I-NPF event). During the cold season without algae farming from January to March,  
107 however, only 7 traditional banana-shaped NPF events were observed out of 54 observation days. Given the air

108 mass back trajectories computed by HYSPLIT model (Draxler and Rolph 2003) were from the northwest inland of  
109 China, these events were defined as continental NPF.

110 The sampling scheme was implemented based on the above size distribution observations. One set of  
111 nano-MOUDI samples was collected during the continental NPF days from February 11 to 13; one set of  
112 nano-MOUDI samples was collected during the non-NPF days from April 16 to 18; one set of nano-MOUDI  
113 samples was collected during the I-NPF days from May 9 to 11 and three sets of daily PM<sub>2.5</sub> samples were collected  
114 during the I-NPF days from April 25 to 27. Each set of nano-MOUDI samples was collected continuously for 72  
115 hours, during which I-NPF or continental NPF occurred on a daily basis, so aerosol chemical composition features  
116 of these two types of NPF events can be observed from offline analysis. In addition, as a comparison to the coastal  
117 site, four sets of PM<sub>2.5</sub> samples were randomly collected on January 14, April 15, April 25 and May 5 at an inland  
118 urban site 200 km from the coast (see Figure 1). The description of the inland site can be found in Yu et al. (2016).  
119 No simultaneous measurement of particle size distribution was made at the inland site.

120 The detailed sampling procedures for PM<sub>2.5</sub> and nano-MOUDI are as follows. PM<sub>2.5</sub> aerosols were collected  
121 on 90 mm quartz fiber filters using a median-volume aerosol sampler (TH-150C, Wuhan Tianhong Ltd., China) at a  
122 flow rate of 100 L min<sup>-1</sup> for 23 h. Since quartz fiber filters may absorb volatile iodine species like hydrogen iodide  
123 (HI), which brings positive artifact to  $\Gamma$  measurement in aerosols, a field blank was collected by placing a HEPA  
124 filter in the upper stream of a quartz fiber filter. Two nano-MOUDIs were placed side by side to collect 10-100 nm  
125 (stages 10-13) and 100 nm-18  $\mu$ m (stages 1-9) aerosols, respectively. Considering low aerosol mass loading on  
126 10-13 stages, the chemical analysis of aerosols collected on 10-13 stages may be sensitive to the particle bounce-off  
127 from upper 1-9 stages. Therefore, aluminum foil filters on the 1-9 stages of the first nano-MOUDI were  
128 silicon-greased to reduce potential bounce-off artifact on the filters of 10-13 stages that were sent for chemical  
129 analysis. For the second nano-MOUDI, all filters were not silicon-greased but only the filters of 1-9 stages were

130 sent for chemical analysis. Before sampling, the filters were baked in a laboratory oven at ca. 500°C for 24 h to  
131 remove organics. After sampling, the filters were packed and stored in a refrigerator below- 20°C.

## 132 2.2 Chemical analysis

133 One-fourth or a half of filter was put in a 10 mL amber vial with 1:1 v/v mixture of water (LCMS grade,  
134 Aladdin, China) and methanol (LCMS grade, Adamas, China). The filter fraction was sonicated for 40 min and the  
135 extract was filtered by a 0.2 µm PTFE membrane syringe filter. The eluate was evaporated to almost dryness in a  
136 rotary evaporator below 40°C and subsequently re-dissolved in 0.5 mL water. After being centrifuged (12000 rpm)  
137 for 30 min, the supernatant was collected for MS analysis using a Waters UPLC (BEH column, 1.7 µm column,  
138 2.1×50mm) coupled with a Xevo G2 Q-TOF MS. A gradient eluent at flow rate 4mL/min was applied as below:  
139 2/98 methanol/water for 0.5 min, linearly increased to 98/2 over 9.5 min, 98/2 held for 2 min, and returned to 2/98  
140 for 3 min. The MS was operated in either positive or negative mode with a TOF resolving power of 32000 FWHM  
141 (ESI+) or 28000 FWHM (ESI-). The MS was externally calibrated daily in the mass range 50–1200 using a 0.5  
142 mM sodium formate solution. A real time Lockmass correction was applied by acquiring leucine-enkephalin  
143 spectrum from a lock spray source. Optimized source parameters were as follows: capillary voltage –2.5 kV for  
144 ESI- (or +3.0 kV for ESI+), desolvation gas flow 600 L h<sup>-1</sup> with temperature 450 °C and source temperature 120 °C.  
145 Depending on the purpose, the QTOF was operated in 3 modes: low energy MS scan mode (in which molecular  
146 ions are subject to in-source fragmentation only), high energy MS scan mode (in which molecular ion are subject to  
147 both in-source fragmentation and collision induced dissociation) and MSMS mode (in which selected precursor  
148 ions are subject to fragmentation with collision induced dissociation before entering TOF). Collision cell voltage  
149 scanned from 10 to 40 eV. Mass spectrum was acquired as continuum format and analyzed by the MassLynx 4.1  
150 software. The procedure of identification and semi-quantification of iodine species would be explained in detail in

151 Section 3. To validate the semi-quantification by our procedure, 20 samples with relatively high iodine  
152 concentration were also analyzed for total soluble iodine using Agilent 7500a ICP-MS (Agilent Technologies,  
153 Santa Clara, CA, USA). To do that, 200  $\mu\text{l}$  aerosol extract was diluted to 5 ml for injection and the iodine detection  
154 limit of the ICP-MS was  $0.1 \mu\text{g L}^{-1}$ .

### 155 3. Result and discussion

156 Section 3.1 first discusses particle number size distribution patterns of two types of NPF events at the coastal  
157 site. Section 3.2 discusses the identification and semi-quantification of iodine species in the ambient aerosols. The  
158 speciation and size distribution of iodine species during the two types of NPF events at the coastal site are shown in  
159 Section 3.3. The comparison of iodine species between the coastal site and the inland site is discussed in Section  
160 3.4.

#### 161 3.1 Particle number size distribution patterns of iodine-induced NPF and continental NPF events

162 Figure 2 shows the particle number size distributions during the two NPF types. During the continental NPF  
163 events (Figure 2a), the production of 2-7 nm neutral particles began at 8:00~9:00 and ceased at around 15:00. New  
164 particle formation appeared to be not associated with the low tide, but followed a nearly identical variation with  
165 both solar radiation and daytime tide height. After the formation, new particles grew to about 100~200 nm in the  
166 midnight, following a typical banana-shape contour (Figure 2a, 1<sup>st</sup> row). These features, together with the air mass  
167 backward trajectories originated from northwest inland of China, confirm that this was a regional-scale continental  
168 NPF event.  $N_{2-20}$ , number concentration of 2-20 nm particles, reached up to  $7 \times 10^4$ - $1.3 \times 10^5 \text{ cm}^{-3}$  during this type of  
169 NPF events, which is higher than the average  $N_{3-20}$   $2.5 \times 10^4 \text{ cm}^{-3}$  during the continental NPF events recorded by us  
170 at Nanjing, the inland urban site in 2016 (Dai et al., 2017).

171 On the I-NPF event days, the production of 2-7 nm began at 9:00~10:00 and last until 18:00 (Figure 2b).  
172 There is a clear time lag of ~4 hours between solar radiation increase and the production of 2-7 nm. High  $N_{2-7}$   
173 (number concentration of 2-7 nm particles) seemed to be associated with low tide during 13:00-15:00.  $N_{2-20}$  reached  
174 up to  $7 \times 10^6 \text{ cm}^{-3}$ - $1 \times 10^7 \text{ cm}^{-3}$ , which is two orders of magnitude higher than those during the continental NPF. The  
175 peak  $N_{2-20}$  values at this coastal site are also one order of magnitude higher than those recorded during the most  
176 intense I-NPF events at Mace Head, Ireland ( $5 \times 10^5$ - $1 \times 10^6 \text{ cm}^{-3}$ ) (O'Dowd et al., 2002). Similar to the NPF events  
177 observed at Mace Head, a clear nucleation mode below 30 nm was seen on each sampling day and particles rarely  
178 grew beyond 30 nm at the coastal site of our study. The “interrupted” growth pattern suggested that the NPF was  
179 limited in a relatively small area around the site. Wild and farmed microalgae at the Xiangshan Gulf were likely the  
180 source of these high concentration nucleation mode particles. In particular, during the harvesting season, the wet  
181 algae have to be dehydrated by exposing them to sunlight for a few days before further processing or transportation.  
182 During this process, a large amount of iodine vapors can be emitted and oxidized to produce new particles.

183 It has been reported from both field and laboratory studies that I-NPF is initiated by a pure negative ion  
184 nucleation of  $\text{HIO}_3$  (Sipilä et al., 2016). We examined neutral, positive and negative nanoparticle concentrations  
185 measured by NAIS during the two types of events. It has been found that during the I-NPF events the negative ion  
186 concentrations were  $100 \pm 102\%$ ,  $8 \pm 13\%$  and  $58 \pm 32\%$  higher than those of positive ions in the size ranges of 0.8-2  
187 nm, 2-7 nm and 7-20 nm, respectively. On the other hand, negative and positive ion concentrations in all  
188 above-mentioned size ranges were almost the same during the continental NPF events (Figure 2a, row 4-6). The  
189 neutral particle concentrations during I-NPF events were higher than those in continental NPF events by two orders  
190 of magnitude; however, the ion concentrations were similar in both types of NPF events, which were in the  
191 concentration range of 100-1000  $\text{cm}^{-3}$  in all size bins. As a result, ion/particle ratios were on the order of  $10^{-5}$  (2-7  
192 nm) and  $10^{-4}$  (7-20 nm) during the I-NPF events and  $10^{-3}$  (2-7 nm) and  $10^{-2}$  (7-20 nm) during the continental NPF

193 events, suggesting the contribution of ions were negligible in both types of NPF events.

### 194 **3.2 Iodine speciation and semi-quantification**

195 The high resolution LC-MS offers the prospect of identifying unknown organic compounds in complex  
196 samples. Previous studies identified unknown organic iodine compounds in disinfected drinking water and seaweed  
197 base on a strategy that the retention time and accurate mass of iodine-containing precursor ions can be selectively  
198 determined by searching their product ion  $\Gamma$  ( $m/z$  126.9) in MS/MS experiments (Ding et al., 2009; Yang et al.,  
199 2016). Unfortunately, their strategy does not work for our aerosol samples because of two difficulties. First, we  
200 found that most of iodine-containing ions in our samples were dissociated to release  $\Gamma$  due to in-source  
201 fragmentation even in the most gentle ionization condition (e.g., low capillary voltage, low source temperature and  
202 desolvation temperature). This can be seen from Figure 3(a) that extracted ion chromatograms of  $m/z$  126.9039  
203 are of similar intensity in low energy MS scan mode (in-source fragmentation only) and high energy MS scan mode  
204 (in-source fragmentation plus collision induced dissociation). In this situation, it is impossible to select  
205 unfragmented iodine-containing precursor ions for MSMS experiments. Second, even if organic iodine compounds  
206 can survive from in-source fragmentation, there are many co-eluting background interfering ions. It is time and  
207 labor consuming to search  $\Gamma$  from all co-eluting molecular ions using MSMS experiments. This often becomes  
208 impractical because small organic iodine ions and other neighboring ions often appear in the same precursor  
209 isolation window of quadrupole.

#### 210 *Iodide-organic adducts*

211 The above in-source fragmentation behavior suggests that a large proportion of iodine-containing substances  
212 in our samples are weakly bound iodide-organic adducts.  $\Gamma$  is an electronegative weak base, which can bind with  
213 hydroxyl, acid or keto groups to form adducts depending upon the polarity and H-bonding capability of

214 organic/inorganic compounds (Lee et al., 2014). This is also the theory that iodide-chemical ionization mass  
215 spectrometry (CIMS) uses I<sup>-</sup> as ionization reagent to measure organics. Our experiment presented in Figure 3b-3d  
216 partly supported the above hypothesis. No I<sup>-</sup> peak was detected after RT 1 min in the extracted m/z 126.9039  
217 chromatograms of pure potassium iodide (KI) solution (1 mmol L<sup>-1</sup>) or an aerosol extract with low concentration of  
218 iodine. However, when the aerosol extract was mixed with KI solution for another analysis, elevated I<sup>-</sup> peaks in low  
219 energy MS scan mode (blue line) indicated the formation of iodide-organic adducts. Furthermore, when collision  
220 induced dissociation was applied, no additional I<sup>-</sup> peaks showed up in high energy MS scan mode (red line). Such  
221 an observation implies that (1) iodide-organic adducts were formed but easily dissociated in the low energy MS  
222 scan mode and (2) no stable organic iodine compounds were formed in the aerosol extract+KI mixture. This is also  
223 confirmed by the fact that no new ions were formed by comparing the mass spectra of aerosol extract before and  
224 after KI addition. Therefore, all m/z 126.9039 peaks after RT=1 min in a sample by low energy MS scan can be  
225 deemed iodide-organic adducts and their total peak area should be proportional to the total concentration of the  
226 adducts.

### 227 *Organic iodine compounds*

228 On the other hand, the identities of those stable organic iodine compounds, i.e., the compounds with C-I bond  
229 that are not or partially dissociated in the ESI source, are still unknown but their atmospheric chemistry may be of  
230 more interest. To bypass the difficulty as discussed above, a signal amplification approach has been applied in this  
231 study to identify these unknown organic iodine compounds, for which the detailed steps are shown in Figure 4. The  
232 approach is analogous to searching a secondary organic aerosol (SOA) tracer in ambient aerosols after its identity  
233 as VOC oxidation product is confirmed by smog chamber simulation. A portion of aerosol extract+KI mixture was  
234 added with H<sub>2</sub>O<sub>2</sub> solution (10 mmol L<sup>-1</sup>). After reaction for 4 h, the mixture was injected for low and high energy

235 MS scans. As compared to the chromatograms of the untreated mixture (Figure 3d), a considerable amount of stable  
236 organic iodine compounds were formed but dissociated only in high energy MS scan (red curve in Figure 3e), in  
237 addition to the formation of more iodide-organic adducts (low energy MS scan, blue curve in Figure 3e). These  
238 organic iodine compounds are believed to form from the reactions between aerosol organics and HOI that is  
239 produced via  $\text{H}_2\text{O}_2 + \text{I}$  reaction.

240 The identities of these organic iodine compounds can be obtained by comparing MS scan mass spectra (low  
241 energy) before and after the  $\text{H}_2\text{O}_2$  addition using mass defect (MD) vs.  $m/z$  diagram. The mass spectrum was  
242 reconstructed by integrating over RT 0-15 min. All ions above background intensity of  $10^4$  are shown in Figure 5 as  
243 dots and circles stand for the samples before and after  $\text{H}_2\text{O}_2$  addition, respectively. Benefiting from the large  
244 negative mass defect of iodine (0.0961), the negative mass defects of organic iodine compounds are in the range of  
245  $-0.3 \sim 0$ , which makes them easy to be distinguished from non-iodine containing ions. Therefore, each red circle  
246 without a black dot in  $-0.3 \sim 0$  mass defect regime in Figure 5 should stand for an organic iodine compound. These  
247 potential organic iodine ions were further selected for MSMS experiments to confirm their fragments contained I.  
248 Four typical aerosol samples collected at the inland site and coastal site were treated using  $\text{H}_2\text{O}_2$  and  $\text{O}_3$  solutions,  
249 respectively, and analyzed using MD vs.  $m/z$  diagrams in both ESI+ and ESI- modes (Step 1, Figure 4). Since mass  
250 assignment is more accurate for an amplified symmetrical peak than a small shoulder peak, the amplification of  
251 organic iodine compound concentrations helps to obtain accurate masses of potential iodine organic compounds in  
252 ambient aerosols. After that, their retention time information in the UPLC was acquired by extracting their ion  
253 chromatograms from low energy MS scan data.

254 In step 2, the elemental compositions of organic iodine compounds were calculated from the accurate masses  
255 within 1 mDa mass tolerance allowing the elements C, H, N, O, S and I and confirmed by their isotope patterns.  
256 The correctness of calculated molecular formulas was further restricted by the matching of at least one sound

257 structure in ChemSpider database. Consequently, a total of 80 formulas (57 in negative mode and 23 in positive  
258 mode) were obtained, each of which should represent an organic iodine compound and its isomers. Because both  
259 H<sub>2</sub>O<sub>2</sub> and O<sub>3</sub> are important oxidants in atmospheric aerosols, the organic iodine compounds formed in Step 1 may  
260 also exist in real aerosol samples via the same reaction mechanism in the atmosphere. Therefore, in Step 3 these  
261 newly identified 80 formulas were searched in real aerosol samples using a targeted screening strategy based on  
262 their accurate mass and retention time. At last, 35 organic iodine formulas were detected, at least once, in our  
263 aerosol samples (Table 1). The other formulas were not detected in any of the aerosol samples, probably due to  
264 their slower production rate or the absence of corresponding organic precursors in the atmosphere. The number of  
265 isomers listed in the second column of Table 1 is based on the number of ion chromatographic peaks observed for  
266 given m/z values in the real aerosol samples. The total 45 isomer peaks, as well as their retention times, are shown  
267 in Figure S1. Hence, there are in total 45 organic iodine compounds detected in our samples.

268 As shown in Table 1, 35 molecular formulas were classified into four groups: 5 non-aromatic formulas and 30  
269 aromatic formulas including 16 CHOI formulas, 3 CHNI formulas and 11 CHONI formulas. The 5 non-aromatic  
270 formulas are assigned to iodoacetic acid, diiodoacetic acid, iodopropenoic acid, iodomethanesulfonic acid and  
271 diiodomethane. The first 4 compounds are electrophilic substitution products of alpha-H of organic acids by I<sup>+</sup> from  
272 HOI or I<sub>2</sub>. Diiodomethane is probably from gas-particle partitioning or the product of iodoform reaction of methyl  
273 ketones. Iodoacetic acid was identified in 9 of 10 samples collected from the coastal and inland sites. Other 4  
274 compounds, however, were mostly found at the coastal site.

275 30 CHOI, CHONI and CHNI formulas are assigned to aromatic compounds that are prone to electrophilic  
276 substitution by I<sup>+</sup>. The formulas observed in ESI<sup>-</sup> mode are expected to have a carboxyl or phenol group, while  
277 those observed in ESI<sup>+</sup> mode should be aromatic or heterocyclic amines. 16 CHOI formulas are iodinated phenols,  
278 substituted benzoic acids or phenolic acids. The 3 most frequently detected formulas are C<sub>8</sub>H<sub>7</sub>O<sub>2</sub>I, C<sub>7</sub>H<sub>5</sub>O<sub>4</sub>I,

279  $C_7H_5O_2I$ . CHONI formulas with 3-5 O atoms detected in ESI- mode are iodinated nitrophenol, nitronaphthol or  
280 nitrobenzoic acid. CHONI formulas with 1 O atom detected in ESI+ mode are iodinated hydroxyaniline, pyridinol,  
281 or quinolinol. The most frequently detected CHONI compounds are  $C_6H_4NO_4I$ ,  $C_{10}H_6NO_3I$  and  $C_6H_4NO_3I$ . CHNI  
282 formulas are heterocyclic amines (i.e., pyrazoles, imidazoles and triazoles), among which  $C_7H_{11}N_2I$  was detected in  
283 4 out of 10 samples.

284 Further assignment of the exact identity for the above formulas is impractical, because these 35 molecular  
285 formulas probably stand for hundreds of isomers, for most of which no commercial standards are available.  
286 Nevertheless, the identities of 4 compounds have been confirmed including iodoacetic acid ( $C_2H_3O_2I$ ),  
287 3-iodo-2-propenoic acid ( $C_3H_3O_2I$ ), 3-iodo-benzoic acid ( $C_7H_5O_2I$ ) and 2-hydroxy-5-iodopyridine ( $C_5H_4NOI$ )  
288 according to the retention times of their commercial standards. These 4 compounds are identifiable because they  
289 have no or very few isomers, of which the commercial standards can be procured. Subsequently, these four  
290 compounds can be used as surrogate standards to semi-quantify the concentrations of other organic iodine species.

### 291 *Inorganic iodine species*

292 In addition to the above organic iodine compounds, some inorganic iodine species were also detected. Figure 6  
293 shows the integrated mass spectrum of molecular ions between RT 0.5-0.7 min obtained by low energy MS scan of  
294 an S13 nano-MOUDI sample (10-18 nm particles) collected during the I-NPF days. The most abundant species is  
295  $IO_3^-$ , followed by  $I^-$  and  $HSO_4^-$ .  $I_3^-$  was also observed, probably due to the adduct formation between  $I^-$  and  $I_2$ .  $IO_2^-$   
296 and  $IO^-$  are detectable, but their abundances are two orders of magnitude lower than  $IO_3^-$ . Iodine oxides  $I_2O_{2.5}$  were  
297 not ionizable by the ESI source, but they might have been hydrated to  $HIO_x$  and detected as  $IO_x^-$  (Sipil äet al. 2016).  
298 Iodide-metal complexes like  $CuI_2^-$ ,  $Cu_2I_3^-$ ,  $ZnI_3^-$  and  $CuI_2(HCN)(HCl)^-$  were observed in  $PM_{2.5}$  samples but not in  
299 size-segregated nano-MOUDI samples.  $Cu^+$  and  $Zn^{2+}$  are typical coarse model components. The observation thus

300 indicated that the iodide-metal complexes detected in the PM<sub>2.5</sub> samples were formed only after fine- and  
301 coarse-mode components were mixed in the sample extract. To avoid artificial formation of iodide-metal  
302 complexes during the sample extraction process, our result highlights the importance of collecting size-segregated  
303 samples instead of PM<sub>2.5</sub> or PM<sub>10</sub>.

#### 304 *Semi-quantification of identified iodine species*

305 So far 35 organic iodine formulas (45 isomer peaks) and 5 inorganic iodine anions have been identified. In  
306 order to know their size distributions and relative abundances in different types of samples, the following strategy  
307 was applied to semi-quantify these iodine species (step 4, Figure 4): external calibration curves of peak area vs.  
308 concentration were established by analyzing standard solutions of KI, KIO<sub>3</sub>, iodoacetic acid, 3-iodo-2-propenoic  
309 acid, 3-iodo-benzoic acid and 2-hydroxy-5-iodopyridine. I<sup>-</sup>, I<sub>3</sub><sup>-</sup> and iodide-organic adducts were quantified using KI  
310 as surrogate standard by assuming their ionization efficiencies are similar in ESI<sup>-</sup> mode. The peak area of  
311 iodide-organic adducts was calculated as the total peak area of extracted ion chromatogram of m/z 126.9039 after  
312 RT 1 min. Iodide-metal complexes like CuI<sub>2</sub><sup>-</sup>, Cu<sub>2</sub>I<sub>3</sub><sup>-</sup>, ZnI<sub>3</sub><sup>-</sup> and CuI<sub>2</sub>(HCN)(HCl)<sup>-</sup>, if present, were also quantified  
313 using KI but counted as I<sup>-</sup>. IO<sub>3</sub><sup>-</sup>, IO<sub>2</sub><sup>-</sup> and IO<sup>-</sup> were quantified using KIO<sub>3</sub> by assuming iodate, iodite and hypoiodite  
314 have similar ionization efficiencies. Iodoacetic acid and 3-iodo-2-propenoic acid were quantified with their  
315 respective standards. The other 3 non-aromatic compounds diiodoacetic acid, iodo-methanesulfonic acid and  
316 diiodomethane were quantified using surrogate standard iodoacetic acid. All CHO and CHNO compounds observed  
317 in ESI<sup>-</sup> mode were quantified using 3-iodo-benzoic acid, because they have similar structure of a carboxyl or  
318 phenol group attached to aromatic rings. All CHNO and CHN compounds observed in ESI<sup>+</sup> mode was quantified  
319 with 2-hydroxy-5-iodopyridine by assuming these aromatic or heterocyclic amines have similar ionization  
320 efficiencies. Due to the low amounts of individual aromatic compounds, a total concentration of all aromatic iodine

321 compounds detected was presented for each sample. Field blanks were processed in the same way and subtracted  
322 from the aerosol samples.

323 There are a few weaknesses in the above-mentioned strategy. First, the use of surrogate standards can only be  
324 regarded as semi-quantification for unassigned species. Second, there is still possibility that some unknown organic  
325 iodine compounds are missed by our method shown in Figure 4. Third, inorganic iodine ions that elute around  
326 0.5-0.7 min are prone to stronger matrix ion suppression effect than organic compounds. The underestimation may  
327 be most serious if there are high concentration of co-eluting sulfate, nitrate and ammonium in the aerosol sample. A  
328 linear regression analysis was conducted between the sum of all iodine species measured by this method and the  
329 total iodine measured by ICP-MS. As shown in Figure 7, the total iodine concentration analyzed by our method is  
330 90.5% on average of that obtained by ICP-MS with a correlation coefficient ( $R^2$ ) 0.942. In spite of the above  
331 uncertainties, our method provided a lower-limit estimate of iodine concentrations in ambient aerosols.

### 332 **3.3 Concentration and size distribution of iodine species during the NPF days at the coastal site**

333 We compared the total concentrations (Figure 8) and mass size distributions (Figure 9) of iodine species in 10  
334 nm-18  $\mu\text{m}$  particles during the I-NPF, continental NPF and non-NPF days at the coastal site. The particle number  
335 size distributions during the same NPF days have been shown in Figure 2. It should be noted that, identical to  
336 previous aerosol iodine speciation studies, the concentration reported here ( $\text{pmol m}^{-3}$ ) is an average over the entire  
337 3 sampling days. Thus, iodine concentrations during the intense NPF periods should be higher than the values  
338 reported in this work. Continuous mass size distribution was fitted from the measured size-segregated mass  
339 concentration data by assuming multimodal lognormal size distributions (Yu et al. 2010). Size distribution of  
340 sulfate ( $\text{HSO}_4^-$ ) was also shown ( $\mu\text{g m}^{-3}$ ) in Figure 9. Because relative distribution in different sizes is not affected  
341 by the uncertainties of semi-quantification, the size distributions are reported here with high confidence.

342 The highest total iodine concentration  $126.3 \text{ pmol m}^{-3}$  was found during the I-NPF days, which was 3.1 and  
343 5.5 times higher than those during the continental NPF and non-NPF events, respectively. As shown in Figure 9a,  
344 all iodine species except iodoacetic acid were characterized by a nucleation mode with mode diameters between  
345 22-35 nm during the I-NPF days. This clearly shows that iodine was the NPF precursor in this type of NPF event.  
346 The most remarkable iodine species during the I-NPF days is  $\text{IO}_3^-$  with a mole fraction of 42.5%. This is consistent  
347 with the recent observation that  $\text{HIO}_3$  is the key nucleating precursor in I-NPF event (Sipilä et al., 2016). On the  
348 other hand, the sum of iodide ( $[\text{I}^-] + [\text{I}_3^-]$ ) and iodide-organic adducts accounted for ~50 % of total iodine in newly  
349 formed iodine particles. The presence of high iodide in clusters or new particles has not been reported by previous  
350 field or laboratory measurements using CI-API-TOF or AMS (O'Dowd et al., 2002; McFiggans et al., 2004; Sipilä  
351 et al., 2016). Iodide is most likely from the partitioning of gaseous precursor HI formed during the photolysis of  $\text{I}_2$   
352 or iodomethane. HI itself is not a good nucleation precursor due to the lack of H-bond or halogen bond, but our  
353 measurement suggests that HI might contribute to new particle growth in the size range as small as 10-18 nm. The  
354 finding of  $\text{HSO}_4^-$  in nucleation mode is also interesting (Figure 6 and 9a), indicating that sulfuric acid also  
355 contributed to new particle growth during the I-NPF days.

356 Although organic iodine compounds were most frequently found in the I-NPF samples (Table 1), they  
357 accounted for only 6.8% of total iodine in the newly formed iodine particles. Considering the short lifetime of new  
358 particles in the atmosphere, they were most likely from the heterogeneous uptake of gaseous HOI (formation route:  
359  $\text{I} \rightarrow \text{IO} \rightarrow \text{HOI}$ ) and subsequent reactions with organics in the new particles. One exception is iodoacetic acid that  
360 was characterized by a smaller accumulation mode and a larger coarse mode. Backward trajectory analysis showed  
361 that air masses moved along the coast from the north during the I-NPF days. The unique size distribution of  
362 iodoacetic acid indicates that direct sea salt emission was probably its major source.

363 Lower iodine concentrations during the continental NPF days and non-NPF days might be due to relatively

364 low iodine emission rate or transformation rate (from gaseous emission to particles) in non-algae growth season or  
365 cloudy days. Iodine during the continental NPF days was characterized by an accumulation mode with mode  
366 diameters between 500-700 nm (Figure 9b), except that iodoacetic acid had a coarse mode and 3-iodo-2-propenoic  
367 acid had a 60 nm Aitken mode. Despite different size distribution from I-NPF, the mole fraction of iodide and  
368 iodide-organic adducts were again ~50% of total iodine during the continental NPF. The outstanding species in the  
369 continental NPF days were aromatic iodine compounds that accounted for 30% of total iodine. This is not  
370 surprising because air masses from inland area of China on these days might contain a large amount of  
371 anthropogenic aromatic substances. The predominance of accumulation mode implies that iodine was unlikely an  
372 important nucleating precursor in the continental NPF. Direct uptake of gaseous HI or HOI onto  
373 accumulation-mode aerosols seems also unlikely, because otherwise iodine should also be present in accumulation  
374 mode during the I-NPF days. It is hypothesized that iodine species in the accumulation mode during the continental  
375 NPF days were from the aging process of small iodine-containing particles. During the aging process, the organic  
376 iodine compounds were formed from aqueous phase reactions between  $I^-$ ,  $H_2O_2/O_3$  and aromatic compounds via  
377 in-cloud processing.

378 Iodoacetic acid and 3-iodo-2-propenoic acid surprisingly accounted for 44.3% of total iodine concentration  
379 ( $22.8 \text{ pmol m}^{-3}$ ) during the non-NPF days. The high iodoacetic acid concentration, together with its presence in  
380 coarse mode, again suggests its unique source associated with sea salt emission. 3-iodo-2-propenoic acid during  
381 the non-NPF days and continental NPF days was characterized by a bimodal distribution with mode diameters  
382 around  $1 \mu\text{m}$  and 50-63 nm. In contrast, the bimodal distribution was replaced by a single small nucleation mode  
383 during the I-NPF days. The sources of 3-iodo-2-propenoic acid and iodoacetic acid became more important during  
384 the non-NPF days and merit more future investigation.

### 385 3.4 Comparison between coastal site and inland site

386 Table 2 gives a comparative overview of iodine species in PM<sub>2.5</sub> between the inland urban site and the coastal  
387 site. The coastal samples include the 3 sets of nano-MOUDI data presented in Figure 8, from which the  
388 concentrations of various iodine species in 10 nm - 3.2 µm particles were extracted to approximate PM<sub>2.5</sub>; the rest  
389 data were acquired by directly analysing the real PM<sub>2.5</sub> samples. It is found that total iodine was in the range of  
390 6.5-11.2 and 19.5-122.6 pmol m<sup>-3</sup> at the inland and coastal sites, respectively. Larger variation of iodine  
391 concentrations at the coastal site is due to the inclusion of both I-NPF and non-NPF samples. The concentrations of  
392 nearly all iodine species at the inland site were lower than those at the coastal site. This indicates that there were no  
393 or relatively weak iodine emission sources surrounding the inland site. Our total iodine concentrations are in the  
394 same order of magnitude as those reported at Mace Head (Gilfedder et al., 2008), an Ireland coastal site where  
395 iodine NPF has long been reported, and Regensburg, an inland site of southern Germany (Wimschneider and  
396 Heumann, 1995), although their maximum values are higher than ours.

397 Negligible amount of iodate (1.1%) was detected in only 1 out of the 4 inland samples. In fact, the  
398 concentration of iodate was also low on the days without I-NPF events at the coastal site (on average 7±1%).  
399 Therefore, iodate is a predominant species only in newly formed particles (Figure 9) and its concentration might be  
400 reduced soon in the aging process via reactions like  $\text{IO}_3^- + \text{I}^- + 6\text{H}^+ \rightarrow 3\text{I}_2 + 3\text{H}_2\text{O}$  (Pechtl et al., 2007). The mole  
401 fractions of iodide were 22.8±9.0% and 30.6±13.8% at the inland and coastal sites, respectively. Following the old  
402 definition, the iodine species other than I<sup>-</sup> and IO<sub>3</sub><sup>-</sup> were calculated as soluble organic iodine (SOI). Our finding is  
403 that newly formed iodine particles were mostly composed of inorganic I<sup>-</sup> and IO<sub>3</sub><sup>-</sup> (68±20 % of the total iodine), but  
404 SOI fraction increased to account for on average 76.3±6.9% of total iodine in the aged particles. Among the SOI  
405 species, the largest fraction 63.7±7.7% was attributed to iodide-organic adducts at the inland site, followed by  
406 aromatic iodine (11.5±2.8%) and iodoacetic acid (1.6±1.0%). All other species were not detectable or of negligible

407 amounts.

408 Table 2 clearly shows that more information on the speciation of soluble organic iodine in the aerosol samples  
409 is provided in this study as compared to previous studies. In particular, a portion of iodine technically defined as  
410 iodide-organic adducts was reported in our study for the first time, because they cannot survive in electrospray  
411 ionization process even in most gentle source conditions, due to the weak bounding strength of I<sup>-</sup> with organics.  
412 I-organic adducts accounted for 63.7±7.7 % in the inland urban samples and 30.8±15.8% in the coastal samples.  
413 Using IC-ICP-MS method, this portion of iodine is likely counted into organic iodine compounds. Our analysis  
414 shows that this portion of iodine adducts can be attributed to neither stable organic iodine compounds nor free I<sup>-</sup> ion.  
415 Under certain condition, e.g., pH value, iodide-organic adducts probably release free I<sup>-</sup> ion in the ambient aerosols.

#### 416 4. Conclusion

417 Intense new particle formation events were observed during the algae growth and farming season at  
418 Xiangshan Gulf, a coastal algaculture area of China. The high iodine concentration in nucleation mode particles  
419 measured by UPLC/Q-TOF-MS confirmed that the NPF events were induced by iodine species. This is the first  
420 study to investigate iodine-induced NPF in a place other than the coast sites of west Europe, Tasmania and Polar  
421 regions. It is known that China produces more than 90 % seaweed of the world (1.5 million tons per year). Iodine is  
422 likely emitted to the atmosphere and transformed to nano particles during the farming, harvesting and processing of  
423 cultivated seaweed. Growing algae population due to serious eutrophication in the coastal waters of China also  
424 promotes iodine emission. Therefore, farmed microalgae, as well as wild algae, could be an important source of  
425 new particle formation in the coastal areas of China.

426 Using UPLC/Q-TOF-MS, inorganic I<sup>-</sup>, IO<sub>x</sub><sup>-</sup> and I<sub>3</sub><sup>-</sup> were easily identified according to their accurate ion mass.  
427 A large portion of iodide was observed to exist as weakly bound iodide-organic adducts. A signal amplification

428 approach was applied to look for organic iodine compounds, i.e., the compounds with C-I bond. For the first time,  
429 35 molecular formulas, or 45 organic compounds according to the number of isomer peaks, were identified in  
430 ambient aerosols. Iodine species on the I-NPF days and continental NPF days were characterized by a nucleation  
431 mode and an accumulation mode, respectively. For the first time, high concentration of I was observed in particles  
432 as small as 10-18 nm, suggesting gaseous HI may contribute to new particle growth in the I-NPF events. Iodate was  
433 a remarkable species in only newly formed particles and was reduced in the aging process. Newly formed iodine  
434 particles were mostly composed of inorganic  $\text{I}^-$  and  $\text{IO}_3^-$ , but SOI ( $[\text{total iodine}] - [\text{I}^-] - [\text{IO}_3^-]$ ) accounted for the  
435 majority of iodine in the aged particles. Generally speaking, organic iodine compounds resided in the same particle  
436 mode as inorganic iodide. The exceptional coarse mode of iodoacetic acid indicates that direct sea salt emission  
437 was probably its major source. During the continental NPF days, the characteristic iodine species is aromatic iodine  
438 compounds that accounted for 30% of total iodine. Those aromatic iodine compounds were probably formed from  
439 aqueous phase reactions between  $\text{I}^-$ ,  $\text{H}_2\text{O}_2/\text{O}_3$  and aromatic organic compounds during in-cloud processing.

440 Our study provided important information of iodine speciation, concentration and its role in NPF in the  
441 context of heavy air pollution in eastern China. However, source, gas-particle partitioning and formation  
442 mechanism of these iodine species are largely speculative. Moreover, the chemical composition and the role of  
443 iodine in cluster sizes (1-3 nm) are still unknown. Simultaneous measurement of gaseous iodine precursors like  $\text{I}_2$ ,  
444  $\text{HI}$ ,  $\text{HIO}_x$  and  $\text{IO}_x$  using online instruments like CI-Api-TOF and DOAS are needed to elucidate the above questions.  
445 On the other hand, more field measurements at multiple sites are required to test on what spatial scale iodine NPF  
446 might be of relevance, in competition with other NPF precursors.

#### 447 ACKNOWLEDGMENTS

Table 1. Organic iodine compounds that were detected at least once in the aerosol samples. n: the number of samples. Four PM<sub>2.5</sub> samples were collected at the inland site; three PM<sub>2.5</sub> samples and three sets of nano-MOUDI samples were collected at the coastal site. m/n numbers in right 4 columns: a given molecular formula was detected in m out of n samples. A blank cell means the formula was not detected in any samples. Also shown are measured ion mass, exact ion mass and the number of isomers based on the number of chromatographic peaks observed for given ion mass in the samples. Bold formulas are observed in ESI+ mode and others in ESI- mode.

Molecular formula	Measured ion mass (Da)	exact ion mass (Da)	Isomer number	Coastal site (n=6)			Inland site (n=4)	All samples

Table 2. Comparison of iodine species in PM<sub>2.5</sub> between the inland urban site and the coastal site. iodide: the sum of I<sup>-</sup>, I<sub>3</sub><sup>-</sup> and I<sup>-</sup>-metal complexes (if present). IO<sub>x</sub><sup>-</sup>: the sum of IO<sub>3</sub><sup>-</sup>, IO<sub>2</sub><sup>-</sup> and IO<sup>-</sup>; SOI: soluble organic iodine that is calculated as the difference between total iodine and the sum of iodide and IO<sub>x</sub><sup>-</sup>. I-AA: the sum of iodoacetic acid and diiodoacetic acid; I-PA: iodopropenoic acid; I-MSA: iodomethanesulfonic acid; CHI<sub>2</sub><sup>-</sup>: diiodomethane; I-aromatics: total aromatic iodine compounds; I-organic adducts: iodide-organic adducts. Also shown are iodine species measured by IC-ICP-MS at Mace Head (Gilfedder et al., 2008), an Ireland coastal site, and Regensburg (Wimschneider and Heumann, 1995), an inland site of southern Germany.

Iodine species	Inland site (n=4)		Coastal site (n=6)		Mace Head, Ireland		Regensburg, Germany	
	Conc. (pmol m <sup>-3</sup> )	%	Conc. (pmol m <sup>-3</sup> )	%	Conc. (pmol m <sup>-3</sup> )	%	Conc (pmol m <sup>-3</sup> )	%
iodide	1.0-3.7	22.8±9.0	3.8-74.1	30.6±13.8	0.3-58	3.7-30	3.1-7.2	12-31
IO <sub>x</sub> <sup>-</sup>	ND-0.087	0.3±0.6	1.5-53.1	23.1±14.0	nd-15	0.1-7.2	12.6-54.2	69-88
SOI	5.4-7.5	76.9±8.6	14.2-66.1	46.3±27.3	3.7-509	69-96		
I-organic adducts	4.3-6.1	63.7±7.7	6.7-62.9	30.8±15.8				
CH <sub>2</sub> I <sup>-</sup>	ND-0.083	0.2±0.4	0.036-0.74	0.4±0.7				
I-AA	0.054-0.25	1.6±1.0	0.57-2.2	4.8±5.6				
I-MSA	ND	0	ND-0.28	0.09±0.12				
I-PA	ND-0.016	0.04±0.07	0.16-5.2	5.9±4.6				
I-aromatics	0.76-1.2	11.5±2.8	0.1-12.3	6.7±6.8				
Total Iodine	6.5-11.2		19.5-122.6		10-532		15.7-61.3	

Figure 1. Locations of two sampling sites: ① the coastal site at Xiangshan Gulf ② the inland urban site that is 200 km from the coast. The blue color indicates the coastal area of China.

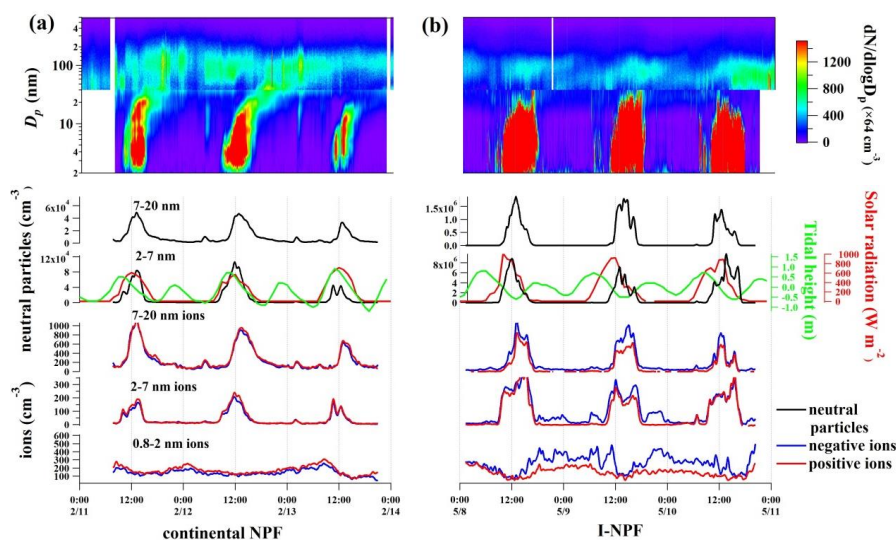

Figure 2. Particle number concentration during (a) the continental NPF days from February 11 to 13, 2018 and (b) the iodine-induced NPF (I-NPF) days from May 8 to 11, 2018. From top to bottom: particle size spectra of the NPF events; diurnal variations of 7-20 nm and 2-7 nm neutral particles (black curves); diurnal variations of 7-20 nm, 2-7 nm and 0.8-2 nm negative (blue curves) and positive ions (red curves). Solar radiation and tidal height were obtained from local maritime authority and plotted as red and green curves, respectively.

Figure 3. Ion chromatograms of  $m/z$  126.9039 of (a) aerosol extract with high concentration of iodine, (b) pure potassium iodide (KI) solution ( $1 \text{ mmol L}^{-1}$ ), (c) aerosol extract with low concentration of iodine, (d) the KI solution mixed with the aerosol extract with low concentration of iodine and (e) The KI solution+aerosol extract mixture with the addition of  $10 \text{ mmol L}^{-1} \text{ H}_2\text{O}_2$  solution. Blue curves: low energy MS scan mode, in which collision induced dissociation is off and molecular ions are subject to in-source fragmentation only. Red curves: high energy MS scan mode, in which molecular ion are subject to both in-source fragmentation and 10-40 eV collision induced dissociation.

	Steps	MS method	Data acquired
1	MD vs. m/z diagram comparison between aerosol and aerosol+KI+H <sub>2</sub> O <sub>2</sub> /O <sub>3</sub>	Low energy MS scan	m/z and RT of potential organic iodine ions
	↓		
2	Elemental composition calculation Chemspider search	MSMS confirmation	80 possible CHONSI chemical formulas
	↓		
3	Targeted screening in real aerosol samples based on m/z and RT	Low energy MS scan	35 formulas (47 organic iodine compounds) and their peak area observed in aerosol samples
	↓		
4	4 compounds quantified with their standards; 43 compounds semi-quantified with surrogate standards	Low energy MS scan of commercial standards	Concentrations of individual non-aromatic compounds and total aromatic iodine compounds

Figure 4. Identification and semi-quantification steps of unknown organic iodine compounds in ambient aerosols

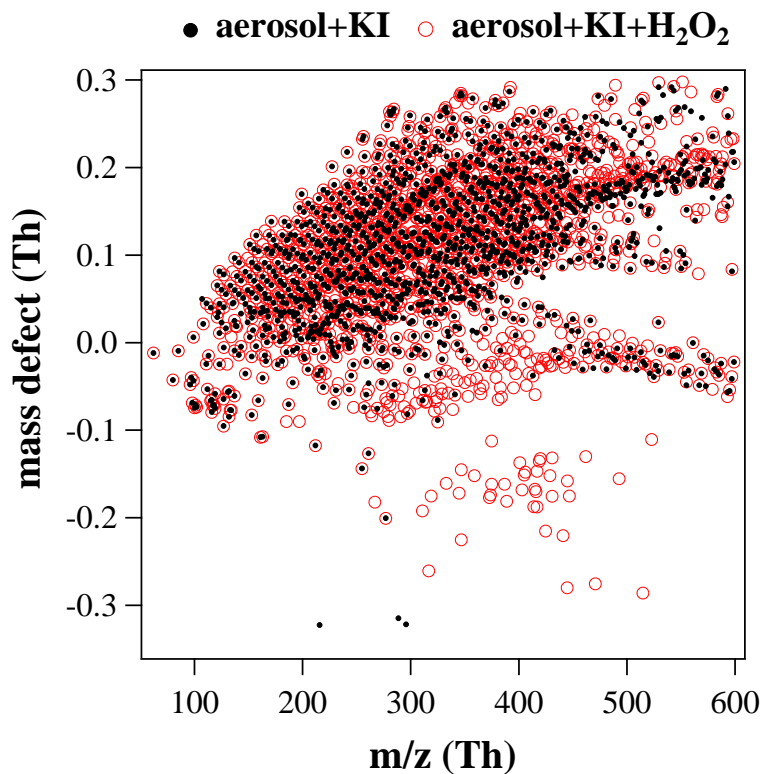

Figure 5. Mass defect (MD) vs.  $m/z$  diagram of molecular ions before (black dots) and after (red circles) the addition of  $\text{H}_2\text{O}_2$  into aerosol extract+KI mixture. The mass spectrum of all ions above background level ( $10^4$ ) was reconstructed by integrating over retention time 0-15 min.

Figure 6. Integrated mass spectrum of molecular ions between retention time 0.5-0.7 min of an S13 nano-MOUDI sample (10-18 nm particles).

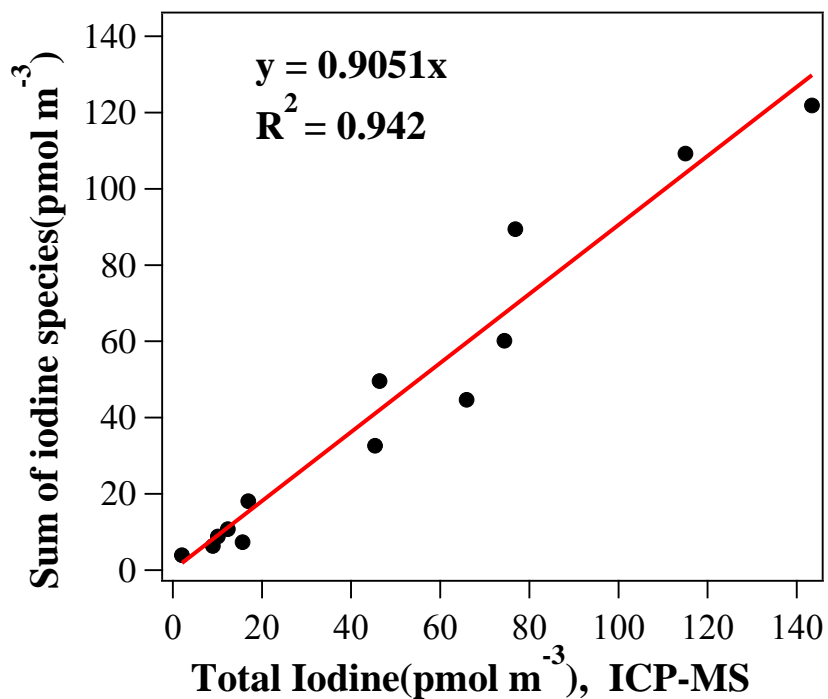

Figure 7. A comparison between the sum of all iodine species measured by our method and total iodine concentration measured by ICP-MS. Red line shows the linear regression between the two methods with a correlation coefficient  $R^2$  0.942.

Figure 8. Total concentrations and mole fractions of iodine species in 10 nm-18 μm particles during the iodine-induced NPF (I-NPF), continental NPF and non-NPF days. I-AA: the sum of iodoacetic acid and diiodoacetic acid; I-PA: iodopropenoic acid; I-MSA: iodomethanesulfonic acid; CH<sub>2</sub>I<sup>-</sup>: diiodomethane; I-aromatics: total aromatic iodine compounds; IO<sub>x</sub><sup>-</sup>: [IO<sub>3</sub><sup>-</sup>]+[IO<sub>2</sub><sup>-</sup>]+[IO<sup>-</sup>]; I-organic adducts: iodide-organic adducts; I<sup>-</sup>+I<sub>3</sub><sup>-</sup>: the sum of iodide and triiodide.

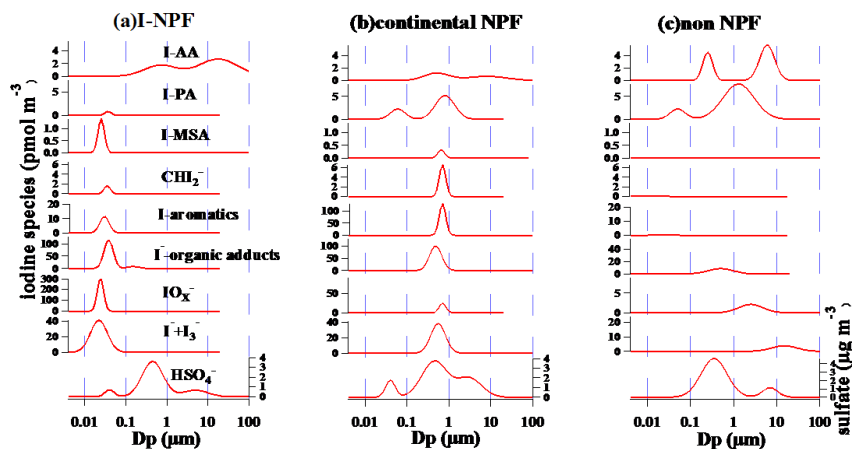

Figure 9. Mass size distribution of iodine species in 10 nm-18  $\mu\text{m}$  particles during (a) iodine-induced NPF (I-NPF), (b) continental NPF and (c) non-NPF days. Continuous size distributions of iodine species were inverted from the measured mass concentrations in the 13 size bins of nano-MOUDI. I-AA: the sum of iodoacetic acid and diiodoacetic acid; I-PA: iodopropenoic acid; I-MSA: iodomethanesulfonic acid;  $\text{CHI}_2$ : diiodomethane; I-aromatics: total aromatic iodine compounds;  $\text{IO}_x^-$ :  $[\text{IO}_3^-] + [\text{IO}_2^-] + [\text{IO}^-]$ ; I-organic adducts: iodide-organic adducts;  $\text{I} + \text{I}_3^-$ : the sum of iodide and triiodide
